For the detection of most viruses, specimens collected soon after the onset of clinical symptoms (preferably within the first 3–4 days) when viral shedding is greatest are preferred. Optimal specimens vary depending on the site or sites of disease. In general, tissues, aspirates, and body fluids are superior to swabs. Body sites or lesions that can be sampled easily with a swab include the pharynx or nasopharynx, conjunctiva, urethra, cervix, vagina, and vesicles or ulcers on the skin or mucous membranes. Many swabs types are available for specimen collection, including plastic swabs, wooden swabs, and swabs with a flexible wire shaft and a tip made of cotton, Dacron, calcium alginate, or polyurethane,[7] although not all are suitable for detection of some viruses. Swabs with a wooden shaft can contain toxic products that inactivate herpes simplex virus (HSV). Cotton-tipped swabs can contain fatty acids that can interfere with the survival of *Chlamydia* species, but they are suitable for the collection of specimens from the vagina, cervix, or urethra for the detection of *Mycoplasma.* Calcium alginate–tipped swabs can be toxic for lipid-enveloped viruses such as herpesviruses and some cell cultures, but they are useful for the collection of specimens for *Chlamydia.* Although swabs placed in a viral transport medium (VTM) can be used for NAATs, many commercial assays for detection of viruses and *Chlamydia* provide their own swab and transport media, which should be used.

Swabs and tissues for detection of viruses should be placed into VTM to prevent drying, maintain virus viability, and prevent the overgrowth of contaminating organisms.[7] Several commercially prepared VTMs are available.[7] Swabs collected for bacterial isolation that are placed in bacterial transport medium are unacceptable for detection of viruses.[7] Conversely, VTM contains antimicrobial agents that inhibit most bacteria and fungi. Specimens such as blood, bone marrow, cerebrospinal fluid (CSF), urine, and other body fluids should be placed in clean, sterile containers without VTM.

For detection of most respiratory viruses, a nasopharyngeal (NP) aspirate or wash, sputum, or bronchoalveolar lavage (BAL) specimen provides a better yield for detection of viruses than NP, nasal, or throat swabs.[7] Multiple samples can be required to maximize yield. Freshly passed stool is superior to a rectal swab for detection of gastrointestinal viruses.[7]

Specific viruses can be found in different blood cells, the plasma or serum, or both (e.g., HIV in lymphocytes and macrophages, CMV in neutrophils and to a lesser extent in mononuclear cells, enteroviruses in plasma and white blood cells).[8,9] Blood should be collected into Vacutainer tubes containing an anticoagulant such as ethylenediaminetetraacetic acid (EDTA). Recovery rates are higher with EDTA than with heparin.[10] Heparin can inactivate herpesviruses and can inhibit some NAATs[11,12]; this issue may be less of a concern for real-time polymerase chain reaction (PCR) and can be related to the type of heparin (sodium vs. lithium) used.[13,14]

For tissue specimens or when the lability of particular viruses (e.g., respiratory syncytial virus [RSV] or varicella-zoster virus [VZV]) is a concern, VTM containing albumin or serum as a stabilizer should be used.

Most viruses are stable for 2 to 3 days at 4°C (refrigerator or wet ice temperature).[7] Freezing at −20°C (ordinary freezer temperature) destroys or reduces the infectivity of most viruses and can alter the ability to detect viral antigen when using some commercially available kits. Beyond 2 to 3 days, specimens should be stored in an ultralow-temperature freezer (−70°C) and transported on dry ice. For some NAATs (e.g., detection of hepatitis C virus [HCV] RNA in serum or plasma), serum or plasma should be separated within 4 to 6 hours of collection and processed within 72 hours (if kept at 2°C–8°C) or frozen at −70°C until tested.[7]

For serologic detection of viral antibodies or antigen, blood can be transported at room temperature. If a delay is anticipated, the specimen should be kept refrigerated at 2°C to 8°C. Serum or plasma should be separated as soon as possible after specimen collection. If an extended period will elapse before testing, the serum or plasma sample should be frozen at −20°C or lower. Repeated freeze-thaw cycles should be avoided. For viruses for which an IgM assay is available (e.g., hepatitis A virus [HAV]), an acute phase specimen can be sufficient for diagnosis. Otherwise, an acute phase specimen is collected within a few days of illness onset and serum is stored, followed by collection of a convalescent phase specimen 2 to 4 weeks later, and the specimens are tested simultaneously.

Virus Detection Methods

Virus Isolation

Most laboratories performing virus isolation use monolayer cell culture techniques. However, many clinically relevant viruses, such as parvovirus, human papillomavirus, hepatitis viruses, Epstein-Barr virus (EBV), rotaviruses, noroviruses, and others, are not cultivatable in routine diagnostic laboratories; laboratory diagnosis is based on other methods. Although cultivation of HIV is possible using suspension cultures of lymphocytes, special containment facilities are required; alternative methods are used for routine diagnosis. The major viruses detected by isolation in monolayer cell culture include HSV-1 and HSV-2, CMV, VZV, RSV, influenza A and B viruses, parainfluenza viruses, respiratory adenoviruses, several enteroviruses (coxsackievirus, echovirus, poliovirus), and measles virus. Not all cultivatable viruses replicate in a single cell line. Thus various cell lines are used for primary isolation: diploid cell lines such as human foreskin or lung fibroblasts for herpesviruses, primary cell lines such as primary rhesus monkey kidney cells for respiratory viruses and enteroviruses, and heteroploid or continuous human epithelial cell lines such as Hep-2 cells for RSV. The types of cell lines used in the diagnostic laboratory are determined by the specimen type, season, epidemiologic data, and clinical information provided. Many viruses cause morphologic changes (i.e., cytopathic effect[(CPE]), in the cell monolayer. Some viruses cause CPE within 2 days (e.g., HSV), others within a week (e.g., enteroviruses), and others after several weeks (e.g., CMV). For viruses that do not cause a typical CPE, detection can be based on the adsorption of red blood cells to the surface of virus-infected cells in culture (e.g., influenza and parainfluenza viruses) or by the use of interference assays (e.g., rubella virus). Presumptive identification of a particular virus or virus group in cell culture is based on the cell type, the timing and appearance of CPE, the source of the specimen, and the suspected clinical diagnosis.

Confirmation of the virus isolated requires immunologic methods such as fluorescein- or peroxidase-conjugated virus-specific monoclonal and polyclonal antibodies. Antibodies to HSV, CMV, VZV, RSV, influenza A and B virus, parainfluenza virus, adenovirus, measles virus, and enterovirus antigens are readily available.

Centrifugation of specimens (referred to as shell vial or spin-amplified culture) onto cell monolayers on coverslips placed in the bottom of small vials or in wells, followed by incubation and staining for viral antigen by using monoclonal antibody after 1 to 3 days, shortens the time required to detect and confirm the presence of many viruses and has replaced conventional cultures in many laboratories. For slowly growing viruses such as CMV, the use of monoclonal antibody against nonstructural proteins produced early in the replication cycle (i.e., immediate early antigen [EA] or EA) allows detection of virus days to weeks before CPE can be observed by traditional cell culture techniques.

Two techniques for isolation of some viruses have been developed with sensitivity comparable to that of standard culture and shell vial methods.[15–17] Genetically engineered cell lines such as the enzyme-linked virus-inducible system (ELVIS, Quidel, San Diego, Calif) using a baby hamster kidney cell line that has been transformed by using an HSV-inducible promoter (*UL39* gene) and an *Escherichia coli* β-galactosidase gene was introduced for the isolation of HSV. The addition of a substrate for the β-galactosidase enzyme results in formation of a color reaction in the HSV-infected cells. This technique has been adapted for performing rapid HSV antiviral susceptibility testing. Mixing multiple cell types in a single shell vial culture can provide rapid detection of the following: respiratory viruses (R-Mix, Quidel); HSV, CMV, and VZV (H&V-Mix, Quidel); and enteroviruses (E-Mix, Quidel).

Antigen Detection

Virus antigen detection tests can be performed directly on a variety of specimen types and are highly specific and rapid.[7] Because virus antigen is cell associated, collection of an adequate number of infected cells is important. Several commercial kits (EIA, latex agglutination, FA) are available for the detection of the following: (1) rotavirus and enteric adenovirus in stool specimens; (2) RSV, influenza A and B viruses, parainfluenza viruses, and adenoviruses in respiratory tract specimens; (3) HBsAg and HIV p24 antigen in serum; (4) HSV and VZV in vesicle or ulcer swab specimens; and (5) CMV in BAL and blood specimens. The FA technique has been used for the detection of rabies virus in brain tissue, mumps virus in throat and urine sediment, and measles virus in conjunctival cells. The detection of CMV pp65 antigen in neutrophils can be used in the diagnosis and management of new or reactivated CMV infection in immunocompromised patients.[18]

Electron Microscopy

Although almost any specimen type is suitable for EM, most laboratories have replaced EM with other virus detection methods.[19,20] Some laboratories continue to use EM for the detection of gastrointestinal pathogens such as rotavirus, enteric adenoviruses, and norovirus, as well as for detection of BK-polyomavirus in tissue biopsy and urine samples.[21–25] Disadvantages of EM include the large number of virus particles (approximately 1 × 10^6/mL of specimen) required for detection, limited throughput, expense, and lack of availability and expertise in many centers.[24]

Nucleic Acid Detection

The increased sensitivity and availability of NAATs for detection of almost any clinically relevant virus have revolutionized testing in the clinical virology laboratory.[19,25–29] In many laboratories, NAATs have supplanted virus culture, antigen detection methods, and direct molecular hybridization techniques. Three approaches have been taken: (1) *target amplification* such as PCR, strand displacement amplification, nucleic acid sequence–based amplification, and transcription-mediated amplification systems; (2) *probe amplification,* including Q-β replicase and ligase chain reaction; and (3) *signal amplification,* such as branched-chain DNA (bDNA) assay and hybrid capture assay.[3,26–32] Several commercial and in-house ("home-brew") assays have been developed. Quantification of viral genome in plasma or serum can be used to determine prognosis, select patients for antiviral therapy, and monitor response to treatment in a variety of patient populations.[28,33] Multiplex assays capable of detecting several viruses in a single amplification reaction have been developed (e.g., for herpesviruses and for enteric, bloodborne, and respiratory viruses), and studies suggest that these assays are cost-effective.[34–39] The development of automated real-time PCR using fluorescence techniques and continuous detection of amplified product has shortened detection times substantially relative to conventional PCR assays.[40] Because these assays use a closed system (i.e., amplification and detection occur in a single tube that need not be opened once the reaction is completed), they also are less prone to contamination than conventional PCR. NAAT has been applied to genotyping of viruses (e.g., HIV, HBV, and HCV), as well as for the detection of mutations that confer resistance to antiviral agents.[28] Newer molecular techniques such as pyrosequencing and whole-genome sequencing are beginning to be applied in the clinical laboratory and are providing improved genotyping of viruses, detection of virus quasispecies, and metagenomic analysis for detecting existing and new or novel viruses in clinical specimens.[41,42]

Choice of Virus Detection Method

Choosing optimal tests depends on the specific virus being sought, clinical setting, specimen type, availability of kits, reagents and equipment, experience of laboratory personnel, and cost. The use of NAATs is rapidly replacing older viral diagnostic methods because of the rapid turnaround time, superior sensitivity, and ability to quantify virus density of NAATs. Several relatively simple in-house and commercially available NAATs are available for a wide variety of viruses. However, some laboratories continue to use antigen detection methods and virus culture when expertise in molecular techniques is not available or cost is prohibitive.

Serologic Methods

Serologic methods can be used to diagnose a current or recent acute infection, to determine specific susceptibility or immunity, and for epidemiologic and surveillance purposes. Interpretation of serologic results is virus specific. For example, the presence of HIV antibodies indicates current infection, whereas the presence of IgG antirubella indicates immunity as a result of immunization or recovery from natural infection. Serologic diagnosis of acute infection is more useful when the incubation period is prolonged (e.g., 3–6 weeks) and antibody is present in serum concomitantly with signs of illness (e.g., EBV and CMV mononucleosis). Fig. 287.1 shows a typical antibody response for an acute, moderate-incubation (several days to 2 weeks) viral illness such as measles. At the onset of rash or other manifestations, antibody is undetectable or is present at low titer. Within 10 to 14 days, appreciable titers of antibody are present. For short-incubation virus infections (e.g., respiratory viruses), a rise in antibody usually does not occur until the late recovery phase or during convalescence and therefore has no value for diagnosis during acute infection. Older serologic methods such as hemagglutination inhibition and complement fixation (CF), which relied on a greater than fourfold rise in antibody titer between acute and convalescent sera tested in parallel, have largely been replaced by solid phase immunoassays such as EIAs, passive latex agglutination, and immunofluoresence assay (IFA). The presence of antibody in high titer in a single serum specimen during convalescence usually does not permit a definitive diagnosis. Seroconversion can be used to diagnose an acute or recent infection.

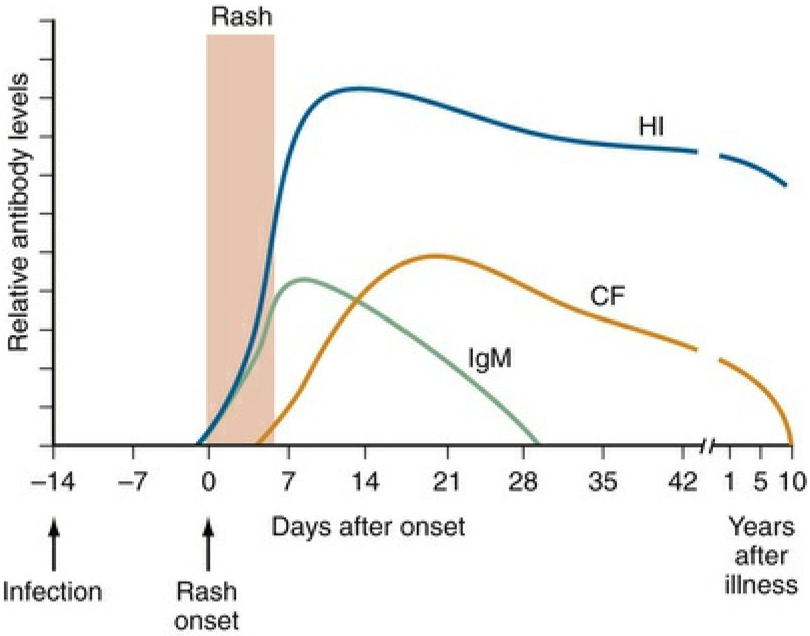

FIGURE 287.1 **Antibody responses during acute measles. CF, complement fixation antibody; HI, hemagglutination inhibition antibody; IgM, immunoglobulin M.**

EIAs and ELISAs are highly standardized, can be quantitative, can detect IgG or IgM antibodies, or both, and, for some viruses such as HIV and HCV, can simultaneously detect both antigen and antibodies in a single assay.[43,44] EIAs can be noncompetitive ("sandwich assay") or competitive assays. Results usually are measured in optical density (OD) units because of a color reaction, and results are reported either qualitatively or quantitatively in international units (IU) or index values. Interpretation of optical density units varies with the EIA-ELISA kit used and the virus antibodies being detected. A relatively newer modification of EIA (known as chemiluminescent immunoassay) uses an enzyme/substrate combination to generate a light signal and results are reported as relative light units (RLU). Chemiluminescent immunoassays generally are considered more sensitive than EIAs.

The presence of virus-specific IgM antibody in serum obtained 1 to 2 weeks after the onset of illness permits a diagnosis of acute or recent infection for many viruses. Typically, IgM antibody disappears from serum within a few months after the acute illness, but it can persist for an extended time in some people and for some viruses.[45] False-positive IgM results can be caused by (1) cross-reactivity (e.g., among herpesviruses or from polyclonal stimulation secondary to EBV infection),[46] (2) the presence of rheumatoid factor (IgM antibody that binds to the Fc portion of IgG),[47] and (3) inherent testing difficulties.[48] Misinterpretation of IgM antibodies as indicative of an acute or recent infection also can occur as a result of (1) persistence of IgM antibody for several months after the acute illness (e.g., EBV, West Nile virus)[49] or (2) reactivation of latent or chronic viruses (e.g., HSV, HBV).

False-negative IgM test results can reflect the following: (1) an absent, low, or delayed IgM response, especially in immunologically immature hosts (e.g., during infancy, congenital CMV or HIV infection) or in immunosuppressed patients (e.g., patients with acquired immunodeficiency syndrome [AIDS])[49,50]; or (2) the presence of high-titer IgG antibody (precluding binding of IgM).[20] Many commercially available kits contain reagents to adsorb IgG from the test serum or use a background subtraction step, thus reducing the possibility of interference.[51,52]

When IgG antibody tests are used to determine susceptibility or immunity to a particular virus, the sensitivity of the method is important. Detection of neutralizing antibodies can be the best predictor of immunity.

The major advantages of serologic diagnosis of acute viral infection include noncritical specimen handling and wide availability. The disadvantages include (1) the requirement for acute and convalescent sera for IgG antibody tests, (2) false-positive and false-negative IgM antibody results, and (3) a delay of 2 to 3 weeks before a diagnosis can be confirmed with short-incubation infections. Because of the many confounding factors (e.g., passive transfer of antibodies from mother to infant, receipt of immunoglobulin, immunocompromise), serologic test results always should be interpreted within the context of the clinical situation. Whenever possible, serologic diagnosis should be confirmed with the use of virus isolation or direct detection of virus antigens or nucleic acids.

Depending on the serologic assay, either serum or plasma can be used. The use of other specimen types has not been well validated for most viruses or assays. Some exceptions include the use of saliva for the detection of HIV antibodies and CSF in patients with viral central nervous system (CNS) disease.[53,54]

Optimal Tests for Specific Viruses

Table 287.1 contains a list of the medically important viruses, major attributable diseases, optimal diagnostic specimens, available tests, and average time to a positive test result. For many tests, the time to obtain a result is a function of the test itself (e.g., culture), the logistics of laboratory testing schedules, or the need to refer a sample to a reference laboratory. The preferred test provides the fastest result with acceptable sensitivity (>90%) and specificity (>95%). The preferred diagnostic test or tests can vary, depending on the patient population being tested (e.g., immunocompromised hosts) and the clinical indication.

TABLE 287.1

Optimal Specimen, Preferred Test, and Performance in Confirmation of Specific Infections

Agent/Type or Site of Infection or Host	Major Diseases	Optimal Specimens	Available Tests[a]	Averag Test Time t Positiv Results
ADENOVIRUS				
Respiratory	Pharyngitis, pneumonia, undifferentiated febrile illness	NP aspirate or wash, NP swab, throat swab, BAL, lung tissue	Culture[c]	6 days
			PCR	1–2 days
			Antigen detection/FA	2 hr
		Serum	IgG antibody[d]	1–5 days
Eye	Conjunctivitis	Conjunctival swab or scraping	Culture[c]	7 days
			Antigen detection	2 hr
		Serum	IgG antibody[c]	1–5 days
Intestinal (types 40 and 41)	Gastroenteritis	Stool	Antigen detection	2 hr
			EM	2 hr
Urinary bladder (immunocompromised host)	Hemorrhagic cystitis	Urine	Culture	6 days
			PCR[c]	1–2 days
			EM	2 hr
ARBOVIRUSES				

SLE, California, WEE, EEE, WNV	Fever, meningoencephalitis	Serum, CSF	IgG and IgM antibody[d]	1–5 days
Colorado tick fever	Fever, malaise, neutropenia	Serum	IgG antibody	7 days
Dengue	Febrile illness with or without rash, hemorrhagic fever	Serum	IgG and IgM antibody[c]	1–5 days
			PCR	1–2 days
CHLAMYDIA/CHLAMYDOPHILA				
Chlamydia trachomatis				
Genital	Urethritis, proctitis, cervicitis, salpingitis, pelvic inflammatory disease	Urethral, cervical swab, first-void urine, self-collected vulvovaginal swab, rectal mucosal swab	NAAT[c]	2–6 hr
			Antigen detection	4 hr
			DNA probe	4 hr
			Culture	48–72 hr
Neonatal	Conjunctivitis, pneumonitis	Eye swab, NP aspirate or wash	NAAT[c]	2–6 hr
			Antigen detection	4 hr
			Culture	48–72 hr
Sexual abuse, rape	Vaginitis, urethritis, proctitis	Cervical, urethral, rectal mucosal swab	Culture[e]	48–72 hr
Chlamydophila pneumoniae (TWAR)	Pneumonia, pharyngitis, bronchitis	NP aspirate or swab, throat swab or wash	Culture[c]	4 days
			Antigen detection	4 hr
		Serum	IgG and IgM antibody	1–5 days
Chlamydia psittaci	Pneumonia	NP aspirate or wash, throat swab or wash	Antigen detection	4 hr
			Culture	2 days
		Serum	IgG antibody[d]	1–5 days
CYTOMEGALOVIRUS				
Congenital	Hepatosplenomegaly, thrombocytopenia, microcephaly, hearing loss, chorioretinitis	Urine, throat swab, EDTA blood, serum, amniotic fluid	Shell vial culture with antigen stain[c]	2 days
			Culture	3–4 wk
			NAAT[f]	2–5 hr
			IgG and IgM antibody[c]	1–2 days
Postnatal infection	Heterophile-negative infectious mononucleosis	Throat swab, urine, EDTA blood	Shell vial culture with antigen stain[c]	2 days
			Culture	3–4 wk
		Serum	IgG and IgM antibody[d]	1–2 days
Immunosuppressed patients	Pneumonitis, colitis, retinitis	EDTA blood	Antigenemia assay[c]	4–6 hr
			NAAT[c,f]	2–5 hr
		Bronchoalveolar lavage, rectal swab, vitreous fluid, tissue biopsy	Shell vial culture with antigen stain[c]	2 days
			Culture	3–4 wk
			NAAT[c,f]	2–5 hr
Pretransplant screening or	Past infection (donor	Serum	IgG antibody	1–2

immune status	and recipient)			days
ENTEROVIRUSES				
Coxsackieviruses groups A and B, echovirus, poliovirus	Aseptic meningitis, fever and rash, herpangina, hand, foot, and mouth disease, myocarditis and pericarditis, paralytic disease	CSF, throat swab, stool, rectal swab, EDTA blood, pericardial fluid, myocardium	Culture	4–7 days
			PCR[c,f]	6 hr
		Serum	Neutralizing[d,g] antibody panel (coxsackievirus group B, echovirus, and poliovirus)	5 days
EPSTEIN-BARR VIRUS				
Healthy person	Mononucleosis syndrome	Serum	Slide agglutination test (monospot)[c]	1–3 days
			EBV-specific IgG and IgM antibody[d]	1–3 days
Immunocompromised	Posttransplant lymphoproliferative disease	Serum, plasma, whole blood, leukocytes	PCR (quantitative)[f]	2–5 hr
GASTROINTESTINAL VIRUSES				
Rotaviruses, Caliciviridae (norovius and sapovirus), enteric adenoviruses, astroviruses	Gastroenteritis	Stool	EM[c] (rotavirus and enteric adenovirus)[c]	2 hr
			PCR[f]	6 hr
GENITAL *MYCOPLASMA* AND *UREAPLASMA*				
Ureaplasma urealyticum	Urethritis, cervicitis	Urethral, cervical swab; semen	Culture[c]	2 days
Mycoplasma hominis	Pneumonitis, meningitis in neonates	Tracheal aspirate, CSF in neonates	Culture[c]	2 days
HEPATITIS VIRUSES				
Hepatitis A	Acute	Serum	IgM antibody	1–2 days
	Immunity	Serum	Total (IgG and IgM) antibody or IgG antibody	1–2 days
Hepatitis B	Acute	Serum	HBsAg, anti-HBc IgM	1–2 days
	Chronic	Serum	HBsAg, anti-HBc total antibody	1–2 days
		Serum or plasma	NAAT for HBV DNA (quantitative)[f]	1 week
	Immunity	Serum	HBsAb	1–2 days
Hepatitis C	Acute	Serum	Anti-HCV EIA screen	1–2 days
			Anti-HCV RIBA supplementary	5 days
	Chronic	Serum or	NAAT for HCV	1 wk

		plasma	RNA (quantitative or qualitative)[f]	
Hepatitis D (only occurs in patients with HBV coinfection/superinfection)	Acute	Serum	HDV Ag, anti-HDV IgM	1–8 days
	Chronic	Serum	HDV Ag, anti-HDV total	1–8 days
Hepatitis E	Acute	Serum	IgG and IgM antibody	1–8 days
HERPES SIMPLEX VIRUS				
Skin, mucous membranes	Oral, genital, cutaneous ulcers or vesicles, herpetic whitlow	Aspirate of vesicle fluid, swab of vesicle fluid or base of ulcer in VTM	Shell vial culture with antigen stain[c,h]	16–24 hr
			Antigen detection (FA)	2 hr
			NAAT[f]	2–5 hr
Past infection	Recurrent genital symptoms but culture results negative	Serum	IgG (group- or type-specific) antibody[d]	1–2 days
Neonatal infection	Disseminated disease; hepatitis; pneumonitis; encephalitis; skin, eye, mouth ulcers or vesicles	Swab of lesions; EDTA blood; CSF; conjunctiva, nose, or mouth swab; rectal swab	Shell vial culture with antigen stain[c,h]	16–24 hr
			Antigen detection (FA)	2 hr
			PCR	2–5 hr
		Serum	IgG and IgM antibody[d]	1–2 days
Ocular infection	Conjunctivitis, keratitis	Conjunctival or corneal swab or scraping in VTM	Shell vial culture with antigen stain[c,h]	16–24 hr
			Antigen detection (FA)	2 hr
			PCR	2–5 hr
Brain or meninges	Encephalitis,[i] meningitis	CSF, brain biopsy[i]	PCR[c,f]	2–5 hr
			Antigen/antibody in CSF	2 hr
			Shell vial culture with antigen stain[h]	16–24 hr
		Serum	IgG and IgM antibody[d]	1–2 days
HUMAN HERPESVIRUS 6				
Primary infection	Roseola (exanthem subitum)	Serum	IgG and IgM antibody[d]	1–3 days
Immunocompromised people	Transplant recipients, AIDS	EDTA blood for PBMCs	PCR[f]	1–2 wk
HUMAN IMMUNODEFICIENCY VIRUS				
Suspected HIV infection in adult or older child	Symptomatic or asymptomatic	Serum	Screening HIV EIA[c]	1–2 days
			Confirmatory Western blot or IFA	1–3 days
			HIV p24 antigen, NAAT[i]	2–4 days
Newborn	Suspected vertical or perinatal	Serum	Screening HIV EIA	1–2 days

	transmission		Confirmatory Western blot or IFA	1–3 days
		EDTA blood	Virus culture	2–3 wk
			NAAT[c,f,i]	1 wk
OTHER VIRUSES				
Human metapneumovirus	Upper respiratory illness, bronchiolitis, pneumonia, croup	NP aspirate or wash, nasal or throat swab, BAL	PCR (including multiplex assays for respiratory viruses)[f]	1 day
Human papillomaviruses	Cervical dysplasia	Cervical swab	RNA probe, hybrid capture, PCR	1–4 days
Influenza viruses	“Flu” syndrome, pneumonia	NP aspirate, wash, or swab; throat swab or wash; BAL	PCR (including multiplex assays for respiratory viruses)[c,f]	1 hr–1 day
			Antigen detection for influenza A and B	30 min-2 hr
			Culture[b]	7–9 days
Measles virus	Measles	NP aspirate or wash	Culture[c]	5 days
		Throat swab	Antigen detection[c]	2 hr
		Serum	IgG and IgM antibody[d]	1–2 days
Mumps virus	Parotitis, aseptic meningitis, meningoencephalitis	Urine, throat swab, saliva, CSF, blood	Culture	8 days
		Serum	IgG and IgM antibody[d]	1–2 days
Parainfluenza viruses	Croup, pneumonitis, bronchiolitis	NP aspirate or wash	Culture[c]	4–7 days
			Antigen detection using FA	2 hr
Parvovirus B19	Erythema infectiosum	Blood, serum, bone marrow, amniotic fluid cells, placental tissue, cord	IgG and IgM antibody[d]	2 days
	Aplastic crisis, congenital, hydrops fetalis		PCR	2 days
Polyomavirus (JC and BK)	JC virus: progressive multifocal leukoencephalopathy (PML)	CSF	PCR	1 wk
	BK virus: polyomavirus-associated nephropathy	Urine	PCR (quantitative)	1 wk
Rabies virus	Encephalomyelitis Immune status after vaccination	Postmortem CNS tissue, antemorem nuchal biopsy	Direct antigen detection (DFA, IHC, DRIT)[c]	24–72 hr
		Serum, CSF	IgG and IgM antibody[d] (IFA)	2 wk 2 wk
		Saliva	Culture	24–72

		(antemortem)		hr
		Serum, CSF	RT-PCR	2 wk
Respiratory syncytial virus	Bronchiolitis, pneumonia, croup	NP aspirate, wash, or swab; throat swab or wash; BAL	Antigen detection[c]	15 min-4 hours
			Shell vial with antigen staining	16–48 hr
			Culture	3–7 days
		Serum	PCR (including multiplex assays for respiratory viruses)	1 hr–1 day
Rhinovirus	Common cold	NP aspirate or wash	Culture	7 days
Rubella	Acquired or congenital rubella	Serum	IgG and IgM antibody[d]	1–2 days
		Throat swab	Culture	5–7 days
VARICELLA-ZOSTER VIRUS				
Skin, disseminated	Chickenpox, herpes zoster, occasional CNS complications	Vesicle fluid, scraping of base of vesicle in VTM, CSF	Antigen detection[c]	2 hr
			Culture	3–7 days
			PCR[c,f]	1 day
		Serum	IgG and IgM antibody[d]	1–2 days
Immune status	Past infection or vaccination	Serum	IgG antibody	1–2 days
MYCOPLASMA PNEUMONIAE	Pneumonia, pharyngitis, Stevens-Johnson syndrome, meningoencephalitis	Throat swab	Culture	3 wk
		CSF	PCR[f]	4–6 days
		Serum	IgG and IgM antibody[c]	1–5 days

[a] Available tests may vary by laboratory. Samples may need to be sent to a reference laboratory for some tests. Not all tests need to be performed in all patients.

[b] The average time to a positive result may be as much a function of the test itself (e.g., culture) as it is the frequency with which the test is performed in the laboratory.

[c] Preferred test on the basis of sensitivity, specificity, and short time to a positive test result.

[d] Acute and convalescent (2–4 weeks after the onset of illness) serologic testing is recommended for most viruses. IgM antibody testing is available for CMV, EBV, HAV, HBVcore, HSV, measles, mumps, parvovirus B19, rubella, and varicella-zoster virus.

[e] In cases of sexual abuse or rape, culture is recommended because of concern about false-positive results with nonculture methods.

[f] PCR test times to a positive result vary.

[g] In the echovirus neutralizing antibody panel, 4 to 5 of the most prevalent recent serotypes are chosen for the panel.

[h] Serotyping of the isolate as HSV-1 or HSV-2 is available.

[i] Detection of proviral DNA after PCR amplification may be the preferred test in young

infants, in adults with mononucleosis syndrome before seroconversion, and in adults with an indeterminate Western blot result.

Ag, antigen; AIDS, acquired immunodeficiency syndrome; BAL, bronchoalveolar lavage; CNS, central nervous system; CSF, cerebrospinal fluid; DFA, direct fluorescent antibody; DRIT, direct rapid immunohistochemical test; EBV, Epstein-Barr virus; EDTA, ethylenediaminetetraacetic acid; EEE, eastern equine encephalomyelitis; EIA, enzyme immunoassay; EM, electron microscopy; FA, fluorescent antibody (detection); HAV, hepatitis A virus; HBc, hepatitis B core; HBsAg, hepatitis B surface antigen; HBV, hepatitis B virus; HCV, hepatitis C virus; HDV, hepatitis D virus; HIV, human immunodeficiency virus; HSV, herpes simplex virus; IFA, indirect fluorescent antigen; Ig, immunoglobulin; IHC, immunohistochemistry; NAAT, nucleic acid amplification test (may include ligase chain reaction, nucleic acid sequence–based amplification, PCR); NP, nasopharyngeal; PBMCs, peripheral blood mononuclear cells; PCR, polymerase chain reaction; RIBA, recombinant immunoblot assay; RT-PCR, reverse transcriptase polymerase chain reaction; SLE, St. Louis encephalitis; TWAR, Taiwan acute respiratory; VTM, viral transport medium; WEE, western equine encephalomyelitis; WNV, West Nile virus.

Herpesviridae

The optimal tests for diagnosis of the members of the Herpesviridae family vary by virus type. For suspected mucocutaneous lesions caused by HSV or VZV, clinical diagnosis is usually sufficient. If laboratory confirmation is required, an aspirate or swab of the vesicular fluid or scraping of the ulcer base placed in VTM is recommended. Other potentially useful samples include blood in EDTA when viremia is suspected (e.g., neonates), CSF in a sterile container when meningitis or encephalitis is suspected, conjunctival swab or corneal scrapings in VTM in suspected cases of herpes keratitis, and tissue biopsy in VTM or frozen (e.g., disseminated HSV and VZV in neonates or immunocompromised patients). In infants, duodenal aspirates also can be collected for suspected neonatal HSV infection. Tests for isolation of virus, direct detection of viral antigen in cells using FA staining (and monoclonal antibodies specific for HSV-1, HSV-2, and VZV), and detection of HSV and VZV DNA by NAATs are all available.

The yield on culture is quite variable and depends on the culture cell type used,[55] the stage of the clinical infection (yield is greatest ≤4 days of onset),[56] and the specimen type and transportation time (preferably ≤12 hours of collection). Visualization of CPE in a sensitive cell line detects 50% of HSV-positive specimens in 24 hours, 80% in 48 hours, and 95% in 72 hours.[57] The shell vial method permits detection of HSV with 66% to 99% sensitivity and 100% specificity by 16 to 24 hours.[55,58] ELVIS has a sensitivity similar to that of both standard and shell vial culture.[15]

Direct detection of VZV antigens by FA of smears from lesions is more sensitive than culture.[59] Vesicular fluid, although good for culture, is inadequate for FA testing because of the lack of cellular material.

Direct antigen detection tests for HSV have variable sensitivity (47%–95%) and specificity (85%–100%).[60,61] None is sufficiently sensitive to detect asymptomatic shedding reliably.[62]

Herpes Simplex Virus and Varicella-Zoster Virus.

The yield of CSF culture is <5% in biopsy-proven cases of HSV encephalitis.[63] HSV PCR performed on CSF (sensitivity of 96% and specificity of 99%)[64] is the diagnostic test of choice for HSV encephalitis and meningitis.[63] PCR results are positive at least through the first 6 to 7 days of illness, even in patients receiving acyclovir therapy.[63,65] Conversely, because negative results were obtained in 1 study in up to 25% of first CSF samples from infants and children,[66] a single HSV PCR test does not completely exclude HSV encephalitis. HSV PCR also is useful with other clinical specimen types,[67] and it can distinguish between HSV-1 and HSV-2. The role of quantitative HSV PCR remains unclear. Results regarding the relationship between the amount of HSV in CSF and clinical outcome are conflicting.[68,69] Successful antiviral therapy is associated with a decline in HSV viral load in CSF.[63]

PCR for detection of VZV DNA is more sensitive than culture or FA, particularly in scrapings of older, crusted lesions. PCR can be used to distinguish vaccine-type versus wild-type VZV. Analysis of CSF by PCR and the detection of VZV antibody in CSF can confirm the role of VZV in CNS syndromes.[70] Multiplex PCR assays, capable of detecting VZV and other herpesviruses, have been evaluated and can simplify the diagnosis in patients with overlapping clinical syndromes (e.g., vesicular rash).[34]

HSV-specific IgG and IgM antibodies are detectable in serum 10 to 20 days after the onset of primary infection. IgG antibodies indicate past, latent, or current infection, but not necessarily active disease. Because Herpesviridae are latent, the presence of HSV IgG antibody in organ transplant recipients is used as a risk factor for recurrences and an indication for the prophylactic use of acyclovir.[71] Because of fluctuations in HSV IgG antibody titers, serologic tests should not be used to diagnose recurrent HSV infections. IgM antibody is not a reliable indicator of primary infection because reactivation can cause a rise in IgM concentrations.[71] Commercially available EIAs, Western blot (WB) tests, and immunoblot tests based on HSV glycoprotein G antigen reliably distinguish type-specific HSV antibodies.[72] The use of HSV-2 type-specific assays has provided important information about the epidemiology of genital HSV infection and the insensitivity of clinical history.[73] Recommendations have been proposed for the appropriate use of HSV-2 serologic tests.[74] No commercially available IgM test can distinguish HSV-1 from HSV-2 infection.

IgG anti-VZV is used primarily to assess susceptibility to infection, to determine the need for vaccination or risk of disease in exposed people, and to determine the duration of protection after vaccination.[75,76] During acute VZV infection, VZV antibodies appear within a few days after the onset of rash and peak 2 to 3 weeks later. A greater than fourfold rise in IgG antibody between serum samples collected 10 to 14 days apart or the detection of VZV-specific IgM antibodies in a single sample supports a diagnosis of acute infection. However, serologic diagnosis of acute VZV infection can be confounded by heterotypic antibody increases that can occur in up to one third of patients with primary HSV infection who have experienced a previous VZV infection.[77] FA against membrane antigen (FAMA) is considered the gold standard for the detection of VZV antibodies.[76] Detection of neutralizing antibodies to VZV in healthy people by FAMA or latex agglutination correlates with protection in up to 96% of people.[78] Occasionally, VZV infection has been reported to occur in patients with low levels of VZV antibodies detected by these assays.[79] EIAs can have lower sensitivity compared with FAMA and latex agglutination assays, particularly for detecting antibodies after vaccination.[76] Newer glycoprotein (gp) EIAs appear to have improved sensitivity over older EIAs. Recognizing the difficulties of serologic testing, the Centers for Disease Control and Prevention consider a history of receipt of 2 valid doses of VZV vaccine as evidence of protection.

Guidelines for standardization of in vitro susceptibility testing of HSV have been published.[80] Resistance to acyclovir and other drugs has emerged as a clinical problem in immunocompromised patients receiving prolonged courses of continuous or intermittent suppressive therapy.[81,82] PCR, together with sequence analysis of the DNA polymerase and thymidine kinase genes, can be used to detect mutations conferring drug resistance.[83] However, this approach is limited because one can interpret the presence only of mutations that have been associated with phenotypic HSV antiviral resistance. The significance of new or novel mutations requires confirmation.

Cytomegalovirus.

CMV can be detected in a variety of clinical specimens by isolation, antigen detection, DNA probes, or NAATs.[84–88] Distinguishing between asymptomatic shedding (from urine, cervical secretions, semen, saliva, and respiratory tract secretions) and active CMV disease is often difficult. Isolation of CMV from tissues is good evidence of active infection. The preferred specimens and tests for detection and diagnosis of CMV depend on the clinical syndrome and immune function of the patient (see Chapter 206).[84,89,90]

To enhance culture detection of CMV in various clinical specimens, multiple shell vials should be inoculated (2 for urine specimens, tissue, and BAL and 3 for blood specimens) with staining at 24 and 48 hours and observation for blood specimens for CPE for 10 days.[91,92] Isolation of CMV from urine obtained during the first 3 weeks of life is diagnostic of congenital infection.[89] In all other situations, distinguishing whether CMV detection is related to primary infection, reactivation or reinfection disease, or asymptomatic shedding (including from respiratory tract specimens) is impossible. In immunocompromised patients with suspected CMV pneumonia, culture of a BAL specimen compared with a lung biopsy specimen has a sensitivity of 70% to 95% and a specificity of 50% to 100%.[93,94] Demonstration of CMV antigen in cells from BAL specimens by direct FA (DFA) staining can be more specific for CMV infection, but sensitivity is reduced.[93] Histologic examination of cells obtained by BAL for the presence of characteristic CMV intranuclear inclusions (“owl eyes” appearance) suggests a diagnosis of CMV pneumonia.

Detection of CMV in blood (peripheral blood white blood cells, plasma, serum, or whole blood) by either CMV antigenemia (pp65 antigen) or CMV PCR can be useful in the diagnosis of active CMV disease or as a predictor of future CMV disease in transplant recipients and other immunocompromised patients.[84,93–99] Results can be quantitative or semiquantitative, and several studies support a relationship between the level of CMV in blood and the likelihood of active or emerging CMV disease.[100–104] These assays are used in preemptive treatment strategies and for monitoring response to anti-CMV therapy. However, because of variability among commercial and in-house quantitative CMV assays, the exact level of CMV DNA or antigenemia that should be used to initiate preemptive therapy is not well established.

For the diagnosis of CMV mononucleosis in otherwise healthy people, testing for CMV-specific IgM is the preferred method. However, IgM antibodies can be detected in both primary and reactivated CMV infections and can persist for months. False-positive CMV IgM test results can occur in patients with acute EBV infection, as well as in patients with high concentrations of rheumatoid factor in the presence of CMV-specific IgG.[105] In immunologically immature hosts or in immunocompromised patients, the CMV IgM response during acute infection can be delayed or absent. Because IgM antibodies do not cross the placenta, their detection in a newborn is diagnostic of congenital infection. However, production of IgM antibodies by the newborn can be delayed or absent in up to 30% of cases, and thus a negative test result does not exclude congenital infection.[89]

The major use of CMV IgG serologic testing is to determine susceptibility to infection in healthcare or childcare workers,[106] as well as to identify the CMV status of blood and organ or tissue donors and recipients.[107] In pregnant women, CMV-specific IgG avidity assays may be of value.[90] The presence of low-avidity IgG anti-CMV can be a better predictor of recent infection than IgM alone, thus increasing the likelihood of CMV transmission to the fetus. However, substantial variability in performance of different CMV avidity assays precludes clear guidance on use and interpretation.[108] Additional testing such as PCR or virus isolation from amniotic fluid may be required to confirm infection of the fetus.

Standardization of in vitro CMV antiviral susceptibility testing has not been established despite the utility of this testing in immunocompromised patients, in whom resistance correlates with clinical failures.[109] Phenotypic assays are limited by long turnaround time and expertise required for performance. Genotypic assays can detect the most common mutations in the CMV *UL97* phosphotransferase gene and the *UL54* DNA polymerase gene that confer antiviral resistance, but these assays are not available widely.[110]

Epstein-Barr Virus.

In patients with suspected EBV infectious mononucleosis (IM), heterophile antibody remains the serologic test of choice.[111] These IgM antibodies can be detected easily and rapidly by using a simple spot agglutination assay (often referred to as a "monospot") or immunochromatographic assays.[112] Heterophile antibodies develop in approximately 80% to 85% of adolescents and adults with EBV IM[111] within 2 to 3 weeks after the onset of illness. Responses can be delayed in some people; repeat testing may be required. Results of the heterophile test can be negative in 70% to 80% of EBV infections in children <4 years of age.[112] Heterophile antibodies usually disappear within a few months but can persist for >1 year after acute illness in 20% to 70% of patients,[49] and persistence should not be interpreted as indicating recurrent or chronic IM. Cases of heterophile-negative IM in school-aged children are caused by CMV in 70% and by EBV (proven by EBV-specific serologic findings) in 16% of cases.[113]

EBV serologic testing can be indicated when the diagnosis of EBV infection is strongly suspected but the heterophile test result is negative.[114] The IFA test is considered the gold standard, although EIA and immunoblot assays can be used.[111] IFA tests have more uniform performance characteristics, whereas EIAs can vary because of the wide variety of antigen preparations used in different kits. The most useful diagnostic test is IgM anti-EBV viral capsid antigen (VCA), which appears within 1 to 2 weeks after the onset of symptoms, disappears within months, and is 91% to 98% sensitive and 99% specific.[49,111,114] False-positive results can reflect the presence of rheumatoid factor, other herpesvirus infections, and antinuclear factors in EIA test systems. False-negative results can occur if samples are collected late in the course of the illness. IgG anti-VCA is elevated during symptoms of illness and can persist for life, and thus it is the most reliable marker of EBV seropositivity. IgG anti–Epstein-Barr nuclear antigen [EBNA]) appears late, generally after 6 weeks, and persists for life. Several months after recovering from IM, a patient is expected to have IgG antibodies to VCA and EBNA, but low or absent VCA IgM antibodies and EA antibodies[111] (see Fig. 208.3).

Direct tests for EBV, such as cultivation in cord blood leukocytes, direct detection by immunofluorescence staining, or detection of DNA,[115,116] are performed in some laboratories. EBV can be isolated from oropharyngeal washings or circulating lymphocytes of 80% to 90% of patients with IM. PCR detection of EBV DNA in the CSF of patients with HIV infection is strongly associated with primary CNS lymphoma.[116] Following organ and marrow transplantation, the use of quantitative EBV PCR using blood specimens can help predict the development of posttransplant lymphoproliferative disease.[117] The relative merit of testing whole blood, leukocytes, plasma, or serum is unclear. Elevated levels of EBV DNA in peripheral blood can be an indication to decrease immunosuppressive therapy or to consider therapies such as $CD20^+$ monoclonal antibodies or EBV-specific cytotoxic T lymphocytes.[117]

Rarely, EBV infection is associated with an acute fulminant disease (e.g., X-linked lymphoproliferative syndrome and virus-associated hemophagocytic syndrome).[118] Persistent high-titer EBV antibodies, except against EBNA, are characteristic but can be absent. The diagnosis depends on detection of virus or its genome.

Human Herpesvirus 6.

Primary infection with human herpesvirus 6 (HHV-6) occurs in most children before the age of 2 to 3 years, and routine laboratory testing usually is not performed. Detectable antibodies in primary infection generally appear 3 to 8 days after the onset of fever. The following serologic criteria are considered diagnostic of primary HHV-6 infection: (1) antibody seroconversion between acute and convalescent phase serum or plasma specimens collected 2 to 4 weeks apart; (2) detection of HHV-6–specific low-avidity IgG antibodies; (3) positive serum IgM in the absence of IgG antibodies; and (4) a greater than fourfold rise in IgG antibody by IFA or anticomplementary immunofluorescence assays.[119] Current commercial assays for IgG anti–HHV-6 do not distinguish between variants A and B and can cross-react with HHV-7 and CMV.[120,121] Antibody avidity testing can be used to differentiate primary HHV-6 from HHV-7 infections. IgM anti–HHV-6 alone is not a reliable indicator of acute or recent infection because IgM can be found during reactivation or reinfection and approximately 5% of adults have detectable IgM anti–HHV-6 at any time.[119] IgM may not be detectable in some culture-positive children.[120,122] During acute primary HHV-6 infection, virus can be isolated from cultures of peripheral blood mononuclear cells (PBMCs) in 100% of infants, but not after recovery.[123] HHV-6 DNA can be detected by PCR both during acute illness and after recovery.[121,124] Monoclonal antibodies are available for direct detection of HHV-6 antigen and have been used to confirm cell culture CPE and for immunohistochemical staining of tissues.

In immunocompromised patients, HHV-6 infection can be associated with substantial morbidity and mortality rates.[125,126] Proof of HHV-6 causation is difficult because specific antibodies can be absent and demonstration of viral DNA in PBMCs can represent latent infection. Although PCR detection of HHV-6 DNA in serum or plasma has low sensitivity, it can be a better marker for active infection. PCR results were negative in the serum or plasma of 57 healthy adults but positive in 94% of 17 patients with exanthem subitum, 23% of 13 bone marrow transplant recipients, and 22% of 18 HIV-infected patients.[127,128]

Human Herpesvirus 7.

Serologic tests for HHV-7 are not available widely. Some degree of cross-reaction between HHV-6 and HHV-7 antibodies results from cross-reactive epitopes on the viruses.[120] Responses can be distinguished by antibody avidity testing.[120] A significant rise in HHV-7 antibodies with stable or absent antibodies to HHV-6 may indicate active infection with HHV-7. HHV-7 has been isolated from the saliva of 75% of healthy adults,[129] as well as from ill people, thus questioning the value of such testing. HHV-7 has been isolated only rarely from PBMCs of healthy asymptomatic people compared with people with active infections; this finding suggests that PBMC cultures may have diagnostic value.[130] Specific primers for PCR amplification of HHV-7 have been developed that do not amplify the DNA from any other human herpesviruses and have been included in a multiplex assay.[131,132]

Human Herpesvirus 8.

Testing for HHV-8 is available only in research settings. PCR has been used for detection of HHV-8 DNA in PBMCs and tissues.[133] The use of plasma or serum for HHV-8 PCR has no value for identifying active infections.[119] Serologic assays can detect IgG anti–HHV-8 but not IgM anti–HHV-8. Although serologic tests are useful for seroprevalence studies, the role of these tests in diagnosing and managing HHV-8 infections has not been established.[134]

Respiratory Viruses

Numerous viruses including RSV, influenza viruses A and B, human parainfluenza viruses (types 1, 2, 3, and 4), adenoviruses (subtypes A to E), rhinoviruses, human coronaviruses 229E, OC43, severe acute respiratory syndrome (SARS) coronavirus, human metapneumovirus (hMPV), and the Middle East Respiratory Coronavirus (MERS CoV) can infect the respiratory tract and cause clinically indistinguishable signs and symptoms. The increasing development of NAATs for detection of respiratory viruses (whether individually or in multiplex PCR assays) has significantly simplified and improved the diagnosis of viral respiratory tract infections.[38,135] NAATs have been applied to NP washes, aspirates, and swabs, as well as BAL and endotracheal tube (ETT) aspirates, with superior sensitivity than culture or antigen detection. Early sample collection (within the first few days of symptom onset) further improves sensitivity. Results with NAATs are available within 1 to 5 hours, thus substantially shortening the turnaround time compared with culture (mean, 3–7 days). When NAATs are not available, some laboratories may continue to use culture or antigen detection tests. The sensitivity of antigen detection techniques (for RSV or influenza viruses, or both) such as EIA microtiter plate kits, membrane filter EIA, and DFA range from 84% to 96%, with a specificity of 92% to 96%.[37,136–140] The membrane filter EIA for RSV detection offers the advantage of providing a result within 15 to 20 minutes.[136–141] Several rapid antigen detection kits, including point-of-care tests, are available for the detection of influenza A only, influenza A and B together (without distinguishing between them), and influenza A or B.[142–150] Evaluations of rapid tests for the detection of seasonal influenza virus, as well as the pandemic 2009 H1N1 virus, indicate relatively poor sensitivity (which is affected by the circulating strains and specimen type) but high specificity. These tests have not been evaluated fully for the detection of avian influenza A/H5N1. When good-quality respiratory specimens with well-preserved epithelial cells are used, DFA staining using monoclonal antibodies has a sensitivity of 80% to 90% and a specificity of >90%.[146–148] Some antigen detection assays can detect multiple respiratory viruses simultaneously.[140] Numerous studies have confirmed the superiority of NAATs for the detection of respiratory viruses, with some tests capable of detecting mutations within influenza strains that confer resistance to neuraminidase inhibitors.[151–155]

The use of serologic tests for the diagnosis of acute respiratory virus infections generally has little clinical value, other than for epidemiologic purposes, and these tests are not routinely available. They play no role in determining immunity or response to vaccine (e.g., influenza virus).[156–160]

Hepatitis Viruses

The routine diagnosis of all infections with hepatitis viruses is based on serologic testing. Serum or plasma can be used and should be separated from blood within 24 hours of collection. The diagnosis of acute HAV infection is made by demonstration of IgM anti-HAV.[156] Immunity to HAV following natural infection or immunization is determined by measuring hepatitis A IgG or total (IgG and IgM) anti-HAV.[156] Currently, no role exists for reverse transcriptase (RT)-PCR measurement of HAV RNA for routine diagnosis, but it can assist in characterizing strains during outbreak investigations.

In acute and chronic HBV infection, both HBsAg and anti–hepatitis B core antibody (HBcAb) usually are present.[157] IgM anti-HBc generally indicates acute HBV infection but can also be detected during a flare of inflammation in chronic carriers. By definition, a person with persistently positive HBsAg for >6 months is considered chronically infected. Isolated anti-HBc positivity can occur during (1) acute infection between the loss of detectable HBsAg and the emergence of detectable HBsAb (“core window”),

(2) late chronic infection when HBsAg levels have fallen to less than detectable levels, (3) coinfection with HCV or HIV that suppresses HBsAg production, (4) infection with a mutant HBV, or (5) a false-positive result. The role of quantitative HBsAg assays is being evaluated for monitoring patients with chronic HBV infection. The presence of HBV e antigen (HBeAg) and the absence of anti-HBe are markers of greater infectivity and correlate with increased risk of progression to chronic hepatitis, cirrhosis, and hepatocellular carcinoma.[157] The presence of anti-HBe is an indicator of likely recovery. The presence of HBsAb at a level >10 IU/mL is considered protective against acute infection. HBsAb levels can decline to less than 10 IU/mL after 10 to 12 years in many vaccine responders. These people remain protected from acute infection likely as a result of immune memory.[158] The presence of HBsAb alone reflects previous immunization, whereas the presence of HBsAb together with HBcAb reflects recovery from previous natural infection.[157] Although HBsAg and HBsAb were believed to be mutually exclusive, as many as one third of carriers of HBsAg will also have detectable HBsAb.[159,160] The mechanism is uncertain, but it may be related to coinfection with different subtypes. Thus current recommendations are that all people who are HBsAb positive be tested for HBsAg at least once.

For diagnosis of HCV infection, second- and third-generation EIAs and a supplementary recombinant immunoblot assay using recombinant structural proteins are widely available.[161,162] Seroconversion occurs by 8 to 12 weeks following acute infection, with a sensitivity of 94% to 100% (except in immunocompromised people) and a specificity of >97% after the supplementary recombinant immunoblot assay test. HCV antibody (anti-HCV) frequently is negative at the onset of jaundice. The presence of HCV antibodies indicates active infection in approximately 70% to 80% of patients. The remaining 20% to 30% of patients have likely cleared the virus spontaneously or as a result of antiviral treatment. The use of HCV RNA assays can help distinguish between these 2 possibilities. No assay is available currently for the detection of IgM anti-HCV. The utility of measuring HCV antigen in serum or plasma has not been established but is being evaluated as a potential alternative to HCV RNA for monitoring patients during therapy.

Molecular assays for the detection and quantification of HBV and HCV viral nucleic acid in serum are useful for determining prognosis, selecting candidates for therapy, and monitoring response to therapy.[161,163,164] A lower baseline concentration indicates a better prognosis and a greater likelihood of response to treatment. Patients responding to antiviral treatment demonstrate a significant drop in HBV DNA or HCV RNA, whereas nonresponders do not. Molecular assays also are available for HBV and HCV genotyping and antiviral resistance testing.[165–167] NAATs that detect HCV RNA in serum 1 to 3 weeks after exposure are being used as part of blood and organ or tissue donor screening and in patients with indeterminate HCV antibody results when the recombinant immunoblot assay result is inconclusive.

In most clinical situations, testing for hepatitis A, B, and C can be grouped into 1 of 3 categories: (1) *acute hepatitis,* (2) *chronic hepatitis,* and (3) *immune status or previous exposure*. For suspected acute hepatitis, initial testing for IgM anti-HAV, HBsAg, and anti-HCV should be performed. If all 3 results are negative, IgM anti-HBc should be tested. Repeat testing for anti-HCV is recommended in 3 to 4 weeks. When chronic hepatitis is suspected, testing should include HBsAg and anti-HCV. Some clinicians also may test for anti-HBc. Patients being screened for immunity or previous infection should have the following tests: (1) total or IgG anti-HAV; (2) HBsAb or HBcAb, or both (depending on whether one is trying to distinguish vaccine response or evidence of previous infection); and (3) anti-HCV (which is a marker of previous infection and not immunity).

Serologic tests are available for both hepatitis D (delta agent) virus (HDV) and hepatitis E virus (HEV), but none is approved by the Food and Drug Administration (FDA).[168] Because infection with HDV occurs solely in conjunction with HBV infection, testing for anti-HDV should be performed in only patients who are acutely or chronically infected with HBV. During coinfection with HBV and HDV, anti-HDV disappears within months following recovery from acute infection. However, in HDV superinfection of a patient who is chronically infected with HBV, anti-HDV generally persists indefinitely because infection becomes chronic in most cases. Measurement of HDV RNA by RT-PCR remains a research test. Both IgG and IgM anti-HEV can be measured using research or commercial assays.[169] Because of the use of different antigens, assays show significant variability in sensitivity and specificity.[170] IgG anti-HEV is positive in most patients 1 to 4 weeks after the onset of disease and becomes undetectable by 3 months. IgG anti-HEV typically declines after infection. In areas where HEV is not endemic, RT-PCR can prove useful as a confirmatory test.

Gastroenteritis Viruses

A multitude of viruses can cause acute gastroenteritis. In most cases, laboratory diagnosis is not required or indicated except perhaps for infection control purposes, during institutional outbreaks, or for public health reasons. Stool samples placed in a clean, sterile container without VTM or preservative for the detection of enteric viruses should be collected within the first 48 hours of illness. Rectal swabs may not contain sufficient virus for EM detection. Stool specimens are stable at 4°C for up to 1 week. Although freezing at −70°C can permit prolonged storage, EM detection is reduced by repeated freezing and thawing that destroys the morphologic features of viral structures. None of the enteric viruses can be cultivated readily in conventional cell culture systems, but all can be detected by EM. Commercial EIA, latex agglutination, and membrane-based tests with >95% sensitivity and specificity are available for detection of rotaviruses, noroviruses, enteric adenoviruses, and astroviruses.[19,20,171] PCR-based assays (including multiplex assays) for these viruses are available commercially,[36,172,173] and they are the methods of choice for diagnosing enteric viruses. Serologic testing for enteric viruses has no clinical role except during outbreak investigations.

Enteroviruses

Enteroviruses generally are stable and survive in the environment for weeks; rapid transport of clinical specimens to the laboratory is not critical. Enterovirus viability decreases slowly over days to weeks at room temperature and is preserved for decades at −70°C. Appropriate specimens include the following: CSF; serum or whole blood; pericardial fluid; tissue biopsy samples (e.g., myocardium); urine; stool; and rectal, nasal, and throat swabs. Although many enteroviruses can be grown in cell culture, some serotypes (e.g., coxsackievirus A groups 1, 19, and 22) fail to grow in standard cell culture. Isolation of enteroviruses requires 4 to 7 days.[174] Virus can be isolated more frequently from stool (80%–85%) and throat swabs (50%–60%) than from CSF (40%–60%) and serum or peripheral leukocytes (40%–50%). Because of the lack of a common antigen among enteroviruses, immunoassays for direct detection are not available. EM is not useful for diagnosis because of the low quantity of virus in most clinical samples.

RT-PCR has been used to test CSF, cardiac tissue, and pericardial fluid, as well as serum, and has significantly improved the speed of detection of enteroviruses, with a reported sensitivity of 81% to 100% and a specificity of 92% to 100%.[175–177] In comparison, culture has a sensitivity of only 40% to 60%.[174] Detection in urine samples is poor, probably because of nonspecific inhibitors of PCR.[178] In respiratory specimens, cross-amplification of some rhinoviruses can occur.

Clinically, the detection of enteroviruses in stool and respiratory specimens must be interpreted cautiously. Asymptomatic shedding of wild enterovirus from the gastrointestinal tract can occur for weeks or months. Additionally, oral polio vaccine virus can be shed in stool and, less commonly, in the throat of young vaccinated children. Detection of virus in CSF, the genitourinary tract, tissue, or blood is proof of a causative role.

Measuring antibody titers for enteroviruses is of limited diagnostic value. A separate neutralization assay must be performed for each enterovirus subtype.

Measles, Mumps, and Rubella Viruses

The laboratory diagnosis of measles, mumps, and rubella (MMR) viruses can be made by virus isolation, detection of antigen, the use of RT-PCR, or serologic testing. Suitable samples for isolation or detection of viral antigen include whole blood (particularly PBMCs for the isolation of measles), serum, buccal swabs, throat and NP secretions, urine, and, under appropriate clinical circumstances, CSF and brain and skin biopsy samples. Because these are labile viruses, rapid transport to the laboratory is important. Specimens are best kept at 4°C before processing, but they can be frozen at −70°C if a delay >48 hours is anticipated. Isolation of virus from blood is greatest 3 to 5 days before rash onset and declines rapidly within 2 to 3 days thereafter. Conjunctival and NP samples for isolation of measles virus can be collected 2 to 4 days before and up to 4 days after the onset of rash. Throat swabs for rubella virus isolation usually are positive (~90%) if collected on the day of rash onset but rapidly become negative within 4 days. Mumps virus can be isolated from saliva 9 days before and up to 8 days after the onset of parotitis. These viruses can be cultivated in conventional cell lines, but isolation requires 7 to 10 days for measles and mumps virus and >3 weeks for rubella virus.[179,180] The shell vial method for measles virus has a sensitivity of 78% at 1 to 2 days and 100% at 5 days. The sensitivity of DFA staining of NP swab specimens for measles virus antigen is 100% compared with culture, but it is only 67% for throat swabs and 85% for urine specimens. Shell vial culture for detection of mumps virus has sensitivity and specificity comparable to those of traditional culture.

Molecular diagnosis using virus-specific RT-PCR has been used for detection of all of 3 viruses and can be used for genotyping to help differentiate wild-type from vaccine-virus strains.[181,182]

Timing of serum specimen collection is critical because many patients do not have IgM antibody at the time of rash onset. For suspected measles virus infection, serum can be collected within 7 to 10 days of rash onset. For rubella virus infection, >90% of patients have IgM positivity ≥5 days after rash onset. Although the traditional MMR serologic test is hemagglutination inhibition for IgG antibody, several IFA and EIA IgG and IgM kits are available commercially.[183] With the declining prevalence of these viral diseases, the positive predictive value of IgM tests can be low. The presence of rheumatoid factor can lead to a false-positive IgM result, and re-exposure in a previously vaccinated person or someone with a history of natural infection can result in a secondary IgG or IgM response. Mumps IgM antibody can persist for months after acute illness.[184] Patients with IM,[185] parvovirus B19 infection,[186] measles virus, and CMV infection can have cross-reacting IgM antirubella antibodies. Similarly, infection with parvovirus B19 and rubella virus can result in cross-reacting IgM antimeasles. In pregnant women, IgM antirubella should be confirmed with a second IgM assay or detection of a significant rise in IgG antibodies.[187] Avidity assays for IgG antibodies to measles and rubella viruses are available. Measurement of virus-specific

IgG antibodies can be used to determine immune status. For mumps virus, cross-reactions with other paramyxoviruses can occur. For rubella virus, an IgG level of >10 IU/mL is thought to represent immunity in most cases.[179]

Human Immunodeficiency Virus

The major diagnostic tests for HIV are serologic (EIA, IFA, and WB for HIV antibody; EIA for p24 antigen), culture, and NAATs for the detection of HIV-1 RNA in plasma or proviral DNA in whole blood or PBMCs. Culture for HIV is no longer used for routine diagnosis.[188] NAATs can be used for the diagnosis of HIV-1 infection in neonates with excellent sensitivity and specificity.[189] Screening tests for HIV-1 RNA have been part of routine blood and organ or tissue donor screening programs since 2002,[190] and these tests also can be used for measuring HIV-1 in other specimen types including CSF, cervical secretions, seminal plasma or semen, and serum. The use of NAATs in people who are not known to be HIV seropositive has yielded false-positive results.[191] The major use of quantitative HIV-1 viral load assays is for monitoring a patient's response to antiretroviral therapy.[27,192] Because of the intra-assay and biologic variability in HIV-1 RNA levels, a greater than threefold change is considered clinically relevant. Different molecular assays also can produce significant differences in HIV-1 viral load, and thus baseline values should be repeated when the laboratory testing is changed from 1 assay to another.[192] Some assays yield lower levels in the same patient if serum is used instead of plasma or if blood is collected in acid-citrate-dextrose anticoagulant rather than EDTA. Currently available commercial assays vary in specimen volume requirement (range, 50 µL to 2 mL), lower limit of detection, dynamic range, and time to result.[193] Regardless of assay format, plasma must be separated from the blood cells within 6 hours of collection. None of these assays is approved for use in people infected with HIV-2 or HIV-1 group O. Other molecular assays are available for HIV-1 genotyping for the detection of antiretroviral resistance mutations.[193] Resistance testing is recommended before initiating therapy and when treatment fails.[194] Phenotypic assays can also be performed for this purpose.

The mainstay of diagnosis for HIV remains HIV-specific serologic testing using screening EIAs or, less commonly, particle agglutination assays followed by confirmatory testing using WB or other assay.[190] Both serum and plasma are acceptable specimens. Testing systems for dried blood spots, urine, and saliva also are available. Third- and fourth-generation EIA kits using more purified virus antigens from cell lysates, recombinant viral proteins, and synthetic peptide antigens can detect group O. These assays have increased sensitivity and specificity and fewer indeterminate results.[190] Most currently available assays detect IgG and IgM anti–HIV-1 and anti–HIV-2 in the same assay.[195] Fourth-generation screening tests can detect both HIV-1 or HIV-2 antibodies and p24 antigen at the same time while reducing the seroconversion window period to approximately 16 days.[190] Detuned (also known as “sensitive/less sensitive”) EIAs capable of measuring the affinity of HIV antibodies have been used to distinguish recent from past or distant HIV infection and to estimate incidence rates.[196]

WB has been the principal confirmatory test for HIV serologic status, even though its sensitivity in seroconversion panels is inferior to that of third- and fourth-generation screening tests. Separate WB tests must be used to confirm HIV-1 and HIV-2. WB measures the antibody response to 9 HIV-1 proteins (p) or glycoproteins (gp): gp160, gp120, p66, p55, p51, gp41, p31, p24, and p17; however, the test is prone to give a high rate of indeterminate results because of detection of cross-reacting antibodies and nonspecific reactions.[190] The criterion for confirmation of HIV-1 infection using WB is the presence of antibody to any 2 of the following: p24, gp41, or gp120/160.[197] No antibody response to HIV-1 proteins represents a negative test result, whereas the presence of some, but not all, antibodies required for a positive interpretation is an indeterminate result. Under these circumstances, repeat testing over the next 6 months is recommended, and if WB results remain indeterminate, patients are considered not to be infected with HIV.[197] In low-risk populations, people with a positive screening EIA test result and an indeterminate WB result are rarely, if ever, infected with HIV on follow-up serologic testing.[198,199] Rapid multispot assays developed as alternatives to WB can distinguish between HIV-1 and HIV-2 with very good sensitivity and specificity.[200]

The IFA test can detect both IgG and IgM anti–HIV-1, is quite sensitive and specific, and has been used as an alternative to WB as a confirmatory test.[190] The line immunoassay can be used for confirmation of HIV-1 (including group O) and HIV-2 in a single test. Rapid point-of-care tests for both screening and confirmation that require minimal or no laboratory equipment have been developed that can yield a result in <30 minutes with sensitivity and specificity comparable to those of third-generation EIA-based tests and other confirmatory assays.[201]

Different laboratory diagnostic strategies are needed for the most common situations in which HIV infection is considered: (1) an *adult or older child who is suspected of having HIV infection,* (2) an *infant with suspected vertically acquired HIV infection,* and (3) someone in whom acute infection or seroconversion may develop because of *exposure to an HIV-infected person*. One should refer to the most recent guidelines from the Centers for Disease Control and Prevention for up-to-date recommendations for screening and confirmation of HIV infection.[202] The most notable change in 2014 was the recommendation to replace WB with HIV-1 and HIV-2 discriminatory assays, p24 antigen tests, and NAATs. The sensitivity of p24 antigen tests varies according to clinical disease status: 4% in asymptomatically infected people, 56% in patients with AIDS-related complex, and 76% in patients with AIDS.[203]

Confirmation of vertical transmission of HIV by using EIA or WB is confounded by the presence of maternal antibodies for up to 18 months of age, and antibody tests should not be used for diagnosis of neonatal infection.[189,204] The current recommendation is that virologic assays (NAATS for HIV RNA and HIV DNA) that directly detect HIV must be used to diagnose HIV infection in infants younger than 18 months of age.[204] HIV culture (once considered the gold standard) and p24 antigen assays should not be used in these situations based on the complexity and cost of culture and the lack of sensitivity of p24 antigen assays.[204–208] Testing in infants with known perinatal HIV exposure is recommended at ages 14 to 21 days, 1 to 2 months, and 4 to 6 months of age.[204] The diagnosis of HIV infection in children with nonperinatal exposure or children with perinatal exposure who are >24 months of age should follow the same recommendations as for testing of adults with suspected HIV infection and is based primarily on the use of HIV antibody tests.

In a person with *known HIV exposure,* antibody to the virus usually can be detected within 2 to 8 weeks after infection. Based on third-generation screening assays, HIV antibodies are detectable in 50% of infected patients within 3 weeks after infection and in most of the remaining patients within 2 months.[190,209] Virtually all infected, immunocompetent people are seropositive 6 months after exposure.[209] A mononucleosis-like syndrome develops in some patients 2 to 4 weeks after infection; p24 antigen can appear transiently during this period.[209]

Arboviruses

Laboratory testing generally is not performed for most arbovirus infections. For arboviruses causing CNS disease, only a brief, low level of viremia occurs, and it clears before the patient seeks medical attention.[210] Thus blood specimens for virus isolation and NAAT rarely yield positive results unless they are collected before the neuroinvasive phase of illness. For some arbovirus infections, including dengue, yellow fever, sandfly fever, Venezuelan encephalitis, and Colorado tick fever, a relatively high level of viremia occurs that can persist for days or weeks and makes virus isolation or NAAT from blood specimens possible. Virus isolation of neurotropic viruses from brain tissue and CSF occasionally is successful during the acute phase of infection; NAAT is more sensitive in these cases.[211]

For most arbovirus infections, the diagnosis is established by IgG seroconversion or detection of specific IgM antibodies, or both.[210,212] Collection of paired acute (collected during the first week of illness) and convalescent (collected 2–3 weeks later) sera is recommended. A single sample may be sufficient for diagnosis if a specific IgM test is available (e.g., eastern equine encephalomyelitis virus, western equine encephalomyelitis virus, California [La Crosse] virus, St. Louis encephalitis virus, West Nile virus, dengue virus). However, in some cases (e.g., West Nile virus), virus-specific IgM can be detected in serum for ≥2 years following infection. For CNS disease, both serum and CSF specimens should be tested. The sensitivity of some of these tests approaches 100% by the 10th day of illness.[213] Traditional assays such as CF and hemagglutination inhibition tests largely have been replaced by FA and EIAs.[210] Serologic cross-reactions can occur among antigenically related viruses (e.g., St. Louis encephalitis, West Nile, Japanese encephalitis, dengue, Powassan, and other flaviviruses). The plaque reduction neutralization test remains the most specific test for the serologic diagnosis of arbovirus infections. Neutralizing antibodies are the best indicators of protective immunity.

Parvovirus B19

Parvovirus cannot be cultivated in routine cell culture, and thus serologic testing (rising IgG titers or the presence of IgM antibody) is the mainstay of diagnosis.[214] IgM antibodies are detectable in serum approximately 10 to 12 days after infection, when the rash or joint symptoms begin, and they can persist for several months. The sensitivity of IgM antiparvovirus exceeds 90% in the first month after the onset of symptoms. IgG antibodies appear several days after IgM and generally persist for years. Current IgG assays have a sensitivity of >90%; IgG indicates past infection. Re-exposure to parvovirus leads to a rise in IgG antibody levels. IgG avidity assays can help distinguish primary from secondary infections.[215] NAAT detection of viral DNA in serum or other specimen types may be required for diagnosis in immunocompromised patients. Parvovirus-associated aplastic crisis, chronic infection, and congenital infection can be diagnosed by PCR testing of serum.[214–216] PCR also can be used to detect parvovirus B19 DNA in bone marrow aspirates, cord blood samples, amniotic fluid cells, and biopsy specimens of placenta and fetal tissues in cases of fetal hydrops. However, parvovirus DNA may be detectable in serum for months after acute infection and for years in other tissues.[217] Thus the diagnosis of acute or chronic parvovirus infection can require both serologic testing and quantitative PCR.

Other Viruses

The recommended specimens and laboratory tests for other viruses are listed in Table 287.1. For most of these viruses, testing is performed in highly specialized research or reference laboratories.

Congenital and Perinatal Viral Infections

The major viruses infecting fetuses and newborn infants now extend beyond the traditional "TORCH" (*Toxoplasma,* rubella virus, CMV, HSV) agents and include CMV, VZV, HSV, rubella, parvovirus B19, HBV, HCV, HEV, enteroviruses, and HIV.[218] Negative maternal and neonatal serologic test results for any of these viruses generally exclude fetal infection.[218] Detection of virus (by culture, antigen detection, or NAAT) can be required before a correct diagnosis can be made. Cord blood can yield false-positive and false-negative results and should not be relied on for diagnosis.[218]

Congenital CMV infection is best diagnosed by isolating CMV from the urine of neonates within the first 3 weeks of life. Beyond 3 weeks of age, isolation of CMV from urine cannot distinguish congenital from perinatal or postnatal infection. IgM anti-CMV in a newborn is positive in only 50% to 70% of congenitally infected neonates, and the test can yield false-positive results.[219]

Congenital VZV infection can be diagnosed by serologic testing. Perinatal or postnatal infection with VZV, as well as infection with HSV and enteroviruses, usually can be diagnosed by conventional antigen detection or culture techniques, although NAAT testing has replaced these tests in most centers. Serologic diagnosis of neonatal HSV infections is inappropriate because a response may not be detectable for 2 or 3 weeks after infection.[220] Demonstration of rubella IgM in a neonate with features consistent with congenital rubella confirms the diagnosis; virus isolation can require 3 to 4 weeks.[218,220,221]

Parvovirus infection during pregnancy can be diagnosed in the mother by serologic testing; detection of IgM or rising IgG antibody concentrations is diagnostic, whereas a stable IgG titer reflects past infection. Parvovirus B19 infection of a fetus with hydrops can be confirmed using NAAT for viral DNA in fetal blood, amniotic fluid cells, or both.[215,221]

Chlamydiaceae

Chlamydia trachomatis, Chlamydophila pneumoniae, and *Chlamydophila psittaci* cause disease in humans. Psittacosis, rare in children, is confirmed serologically.

Chlamydia Trachomatis

Both culture and nonculture methods are available for the detection of *C. trachomatis.* Culture previously was considered the gold standard because of its 100% specificity and excellent sensitivity when optimal techniques were used.[222] However, for genital specimens, its sensitivity is approximately 70% to 80% compared with NAATs, which have now become the tests of choice for routine testing. Testing of first-void urine in men and women by any of the commercially available NAATs has excellent sensitivity and a specificity of >97%, resulting in a high positive predictive value.[223] Other nonculture methods such as EIA and IFA tests and nucleic acid probe tests have little if any role in routine testing for *C. trachomatis* because of their inferior perfomance.[222,224] Point-of-care tests have poor sensitivity and specificity and are not recommended.[225,226]

The optimal specimen types, collection method, and transportation requirements vary depending on the testing method used, the purpose of the test (screening vs. diagnosis), and the age and sex of patients being tested. In general, because of the lower sensitivity, technical requirements, and prolonged turnaround time, culture is not performed routinely for detection of urogenital *C. trachomatis* infection. Culture has been replaced by NAAT as the test of choice. For male patients, either a urethral swab inserted 3 to 4 cm or a first-catch urine sample is the preferred specimen. For women, a swab of the cervical os inserted 1 to 2 cm, a vaginal swab (including self-collected vulvovaginal swab), and a first-catch urine sample are all acceptable specimens.[222,226] NAATs have been used for adult sexual assault victims, and their implications have been assessed.[227] Although NAATs have been evaluated in sexually abused children and their medical and legal implications have been evaluated,[228,229] culture remains the recommended method for urethral specimens from boys and for extragenital specimens (pharynx, conjunctiva, and rectum) from boys and girls.[224] NAATs can be used for vaginal specimens or urine specimens from girls. However, none of the commercially available NAATs is FDA approved for use for testing specimens from extragenital sites. The yield of culture is related directly to the quality of the specimen and the transport and storage conditions before testing. Isolation of *C. trachomatis* in culture from urethral specimens collected from prepubertal boys is low and is not recommended. However, if urethral discharge is present, a meatal specimen can be collected.

Because of the low yield, pharyngeal specimens for isolation of *C. trachomatis* are not recommended for children of either sex.[224]

For culture, Dacron-, cotton- or rayon-tip swabs on an aluminum or plastic shaft are recommended. Swabs with wooden shafts and those with a calcium alginate tip can inhibit growth of the organism.[222] Swabs should be placed immediately into chlamydial transport media (containing sucrose phosphate or sucrose phosphate glutamate supplemented with bovine serum and antimicrobial agents) at 2°C to 8°C and transported to the laboratory within 24 hours. Freezing at −70°C can result in a 20% loss of viability. Freezing at −20°C should be avoided.

Collection of endocervical and urethral swab specimens for NAATs should follow the instructions of the manufacturer. Swab specimens for NAAT are stable at room temperature for up to 10 days. Urine specimens for NAAT are stable for up to 24 hours at room temperature, after which they can be refrigerated for up to 4 days or stored at −20°C or lower for up to 2 months before processing.

Several FDA-approved NAATs are available for the simultaneous detection of *C. trachomatis* and *Neisseria gonorrhoeae* based on PCR, transcription-mediated amplification, and strand displacement amplification.[222] All have excellent sensitivity and specificity and can be performed in 2 to 5 hours. However, they do not all perform equally well with all specimen types.[230] In 2006, a genetic variant of *C. trachomatis* was identified in Sweden that was undetectable by PCR, a finding that further raises the importance of continued assessment of different NAATs to ensure optimal performance.[231]

Serologic tests for *C. trachomatis* genital tract infections are not useful for diagnosis in individual patients.[222] Antibodies to *C. trachomatis* persist for life. In infants, detection of anti–*C. trachomatis* IgM antibody by using the microimmunofluorescence (MIF) test is the diagnostic test of choice for chlamydial pneumonia.[222] Maternal IgG antibodies can persist in infants for 6 to 9 months.[222] The MIF test is the most sensitive serologic test and is the only one that detects species- and serovar-specific responses.[222] EIAs for the detection of IgM antibodies in infants have variable performance compared with the MIF test and are not specific for *C. trachomatis*.[222] Interpretation of a single IgG antibody test result is difficult because 50% to 70% of people can have antibodies to *C. pneumoniae.*[232,233] CF tests have been used widely for the diagnosis of psittacosis and lymphogranuloma venereum, but they have no value in diagnosing genital tract or neonatal chlamydial infections.

Antimicrobial susceptibility testing for any of the *Chlamydia* species has not been standardized, and in vitro results do not necessarily correlate with clinical response to treatment. Therefore, no role exists for routine susceptibility testing for clinical management, and testing generally is restricted to a few research laboratories.

Chlamydophila Pneumoniae

Accurate laboratory confirmation of acute infection with *C. pneumoniae* is difficult and often is based on serologic testing despite the high seroprevalence of the organism in adults.[222,234,235] The MIF test appears to be the most reliable serologic test for diagnosis of acute infection, and the following criteria for a positive test have been used: (1) a greater than fourfold rise in titer; (2) IgM titer >1 : 16; or (3) IgG titer >1 : 512. IgG titers between 1 : 16 and 1 : 512 are considered evidence of previous, but not necessarily recent, infection.[233] However, the MIF test is limited by lack of standardization and availability of high-quality reagents and by the inability to distinguish past from persistent infection.[236] Comparison of EIAs (using species-specific assays) with MIF have shown good sensitivity and specificity in children with respiratory tract diseases and in control children.[237] Because some EIAs detect antibodies to lipopolysaccharide, these tests detect antibodies to all *Chlamydia* species. Given their poor sensitivity, CF tests should not be used for diagnosis.[233,238]

Isolation of *C. pneumoniae* is difficult. The stability of *C. pneumoniae* in clinical specimens has not been well studied, although 1 study reported that 70% of organisms remain viable after 24 hours at 4°C.[222,239] Throat swabs, sputum, NP, BAL, and other respiratory tract specimens placed in transport media have been used with variable success. Detection of the organism in respiratory secretions does not prove causality because asymptomatic infections occur in children and persistent shedding can occur for months after acute disease in adults.[240,241]

Molecular diagnosis with noncommercial conventional and real-time PCR tests has been evaluated.[242,243] Sensitivities appear to be as good as those of culture, but specificity is difficult to determine given the lack of a gold standard for comparison.

Mycoplasma

Mycoplasma Pneumoniae

Rapid and accurate diagnosis of *Mycoplasma pneumoniae* infection is problematic because of the lack of well-standardized tests.[244] Culture is the most widely accepted method for testing respiratory tract secretions, but availability is limited, specialized broth and agar media are required, and yield is relatively low.[245] For optimal isolation, specimens (BAL, tracheobronchial secretions, sputum, NP aspirates or swabs, tissues, blood, CSF, joint fluid) should be inoculated into appropriate media (e.g., SP4) at the bedside. Most media are acceptable for both isolation and PCR assay. Specimens should be refrigerated if they are not processed within 24 hours. Because *M. pneumoniae* is relatively slow growing, cultures should be maintained for 4 weeks before results are reported as negative. Shedding of *M. pneumoniae* can persist for several weeks after the onset of illness (particularly in children), thereby confounding the interpretation of a positive culture result.

Direct antigen testing (EIA, DFA, immunoblotting) for respiratory tract secretions such as sputum and NP aspirates performs well in research settings (sensitivity of 90%), but these tests are not available widely.[246,247] Cross-reactivity with other commensal mycoplasmas can occur. Persistent shedding and detection of antigen in asymptomatic people confound the interpretation of positive results. At present, these tests are neither recommended nor used routinely in the clinical setting.

Conventional and real-time PCR tests for detection of *M. pneumoniae* in respiratory secretions have been widely evaluated.[245–251] PCR tests consistently are more sensitive than culture and antigen detection. Despite relatively high sensitivity, most studies suggest that PCR cannot be used alone to make a diagnosis of acute or recent infection; results must be used in conjunction with other results such as those of serologic tests.[245,251,252] When performed on CSF, PCR can be useful for the diagnosis of *M. pneumoniae*–associated meningoencephalitis.[253]

Serologic diagnosis by measurement of anti–*M. pneumoniae* IgG, IgM, and IgA antibodies can be performed with commercially available EIA, FA, and latex agglutination kits. These tests are more sensitive and specific than CF assays and have replaced CF in many diagnostic laboratories.[244,254,255] Their usefulness is limited because many children are IgM negative at the time of presentation, and the time to seroconversion can be 2 to 4 weeks.[256] In children, adolescents, and young adults, a single positive IgM result can be considered diagnostic, although false-positive results occur. The combination of serologic results together with culture or PCR may provide the most reliable approach to diagnosis.[245,250,251]

Cold agglutinin antibody titers are simple to perform and are widely available. Because only 50% to 75% of people infected with *M. pneumoniae* develop cold agglutinin antibodies and the test lacks sensitivity and specificity, it should not be used for the serologic diagnosis of *M. pneumoniae* infections.[257,258]

Genital Mycoplasmas

The laboratory diagnosis of *Ureaplasma urealyticum* and *Mycoplasma hominis* infections can be achieved by isolation of the organism by using specialized broth and agar media. Organisms grow rapidly, and culture results are positive within 2 to 5 days. PCR (including multiplex assays) has been used to detect *U. urealyticum* and *M. hominis* in clinical specimens.[259–261] *Mycoplasma genitalium* grows slowly; cultures may not be positive for ≥6 days. PCR-based assays are the mainstays of diagnosis,[259,262,263] but none is available commercially. Serologic tests for genital mycoplasmas have not been standardized, and none is available commercially. Serologic testing (using EIA, WB, IFA) has little utility except as an epidemiologic tool.[264] *M. genitalium* cross-reacts strongly with *M. pneumoniae*. Patients with invasive *M. hominis* infection almost always have seroconversion or a significant rise in antibody titer.

Laboratory Manifestations of Infectious Diseases

Sarah S. Long, Jennifer Vodzak

Acute Phase Response

Stimuli of many kinds, including infection, trauma, or ischemia, cause marginalization, extravasation, and activation of neutrophils and monocytes with release of multiple proinflammatory cytokines, including interleukin1β (IL-1β), IL-6, IL-8, and tumor necrosis factor-α (TNF-α). These mediators stimulate production of a variety of proteins referred to as acute phase reactants in macrophages, monocytes, and reticuloendothelial organs with predictable, complex metabolic effects (Box 288.1). The host-pathogen, damage-response framework conceptualizes consequences of such events, which can be caused primarily by the pathogen or the host and can be beneficial or detrimental to the host.[1] More than 100 "biomarkers" have been investigated in infection, and they have been correlated with initiation, magnitude, type, ascent, descent, and duration of acute phase response. Although measurement provides a guide to the intensity of inflammation or the extent of tissue damage, no single marker has exquisite predictive value as a stand-alone test to trump clinical judgment to initiate, withhold, or conclude antimicrobial therapy; instead, these markers augment clinical judgment. Use of combinations of biomarkers in clinical decision rules likely is or will be superior, but complexity makes practical implementation difficult.[2,3] Multiple biomarker panels based on genome-wide expression profiling by stimulus are under active investigation, with measurements of procalcitonin (PCT), IL-6, and IL-8 furthest along. As technology and knowledge of immune modulation advance, biomarker analyses will need to be accessible, rapid, reliable, and studied in prospective trials powered for proof of clinical validity and impact on quality of care before clinical adoption.[4–8]

Box 288.1

Expected Manifestations of the Acute Phase Response

Brain

Increased release of corticotropin, endorphin, prolactin, neuropeptides, and neurotransmitters

Increased production of thyroid-stimulating hormone, vasopressin, insulin, and glucagon

Decreased production of insulin-like growth factor I

Fever, diminished appetite, and somnolence

Blood Cells

Neutrophilia, increased neutrophil activation, and redistribution

Thrombocytosis

Reticulocytopenia, eosinopenia

Activation of B lymphocytes (antibody production) and T lymphocytes (lymphokine production)

Redistribution lymphopenia

Anemia of chronic disease

Tissue

Collagen proliferation by fibroblasts

Demineralization of bone

Proteolysis and amino acid release from muscle

Liver and Other Sites

Increased synthesis or release of complement components and expression of receptors, fibronectin, fibrinogen, mannose-binding protein, lipopolysaccharide-binding protein, hepcidin, ferritin, glycoproteins, C-reactive protein, α_1-antitrypsin, α_2-macroglobulin, lipids and lipoproteins, and ceruloplasmin

Increased synthesis of serum amyloid A, haptoglobin, and immunoglobulins

Decreased free and total serum iron, zinc, and retinol

Decreased synthesis of albumin, prealbumin and transferrin and cytochromes

Decreased gluconeogenesis

Erythrocyte Sedimentation Rate

Physiology and Measurement

The erythrocyte sedimentation rate (ESR) measures in vitro the fall of the red blood cell (RBC) column in a vertical suspension of anticoagulated plasma over 60 minutes. A surrogate of in vivo inflammation, the ESR generally rises over 24 to 48 hours after stimulus and returns to baseline more slowly than other acute phase reactants, thus lagging behind resolution of illness. Sedimentation depends on RBC mass, volume, and shape, as well as RBC-RBC forces and the protein constitution of plasma. Electrostatic forces normally cause RBCs to repel each other and inhibit their aggregation. Increased amounts of plasma fibrinogen or globulins coat the RBCs, foster aggregation, and hasten settling, consequently elevating the ESR. Large-molecular-weight, needle-shaped fibrinogen has the greatest effect, followed by β-globulins and distantly by α_2-globulins, γ-globulins, and albumin.

Normal values are age and sex dependent (androgens lowering the ESR): ≤10 to 20 mm/hr for children 1 month to 12 years old, ≤15 mm/hr for boys and men >12 years of age, and ≤20 mm/hr for girls and women >12 years of age. After puberty, the normal top value rises 0.85 mm/hr for every 5-year increase in age. Obese children have higher mean ESRs than lean children (e.g., 20 vs. 10 mm/hr at 9–10 years of age).[9,10]

Elevated Sedimentation Rate

The ESR is elevated in most bacterial, mycobacterial, and fungal infections and is normal or mildly elevated in uncomplicated viral, rickettsial, and ehrlichial infections. An elevated ESR (>20 or >30 mm/hr, depending on the study) has poor discriminating power as a single test (i.e., sensitivity and specificity ≤50%) to predict bacterial infection in children with nonspecific, febrile illnesses of short duration.[11–13] The mean ESR during most viral upper respiratory tract infections is approximately 20 mm/hr (with 90% of values <30 mm/hr), with noteworthy exceptions such as during adenovirus infections, in which mean ESR can be 40 mm/hr.[12,14] For patients with fever of unknown origin, a normal or mildly elevated ESR is predictive of the eventual diagnosis of a nonserious or viral disease in >90% of cases[15,16]; an ESR >50 mm/hr in such patients can be an impetus for more extensive evaluation.[17,18]

Usefulness of the ESR in children with osteoarticular conditions has been studied.[19] Several studies of children with bacterial arthritis have documented ESRs >30 mm/hr in 80% to 90% of cases (mean, ~65 mm/hr).[20–23] Prospective validation of Kocher criteria (fever ≥38.5°C, inability to bear weight, ESR ≥40 mm/hr, and white blood cell [WBC] count >12,000 cells/mm^3) for distinguishing pyogenic arthritis of the hip from toxic synovitis showed an area under the receiver operating characteristic (ROC) curve of 0.86.[21] In a retrospective case series in a primary referral hospital, positivity of all 4 Kocher criteria in addition to C-reactive protein (CRP) ≥2 mg/dL had a predictive value of only 60% for bacterial arthritis,[22] and in series from the United States and Europe, Kocher scores were low in children with Lyme and *Kingella* arthritis of the hip.[24,25] In children with pyogenic arthritis, the ESR frequently rises on days 2 to 4 of effective therapy,[19] and an ESR >30 mm/hr persists in at least 50% of cases at the conclusion of successful therapy.[19,20] The peak ESR in acute osteomyelitis generally is lower than in bacterial arthritis (mean, ~45 mm/hr), with expectations of a gradual fall and normal values at an appropriate conclusion of therapy.[26] In subacute or chronic osteomyelitis, the ESR usually is mildly elevated (25–40 mm/hr) but can be normal.

An elevated ESR characteristically occurs in multiple noninfectious inflammatory conditions, as well as in noninflammatory states that affect RBC stearic properties or plasma volume, fibrinogen, globulins, or protein concentrations (Box 288.2). Conversely, during infectious diseases, certain conditions can result in a “falsely” low ESR.[27] The ESR usually exceeds 30 mm/hr during febrile episodes in children with periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis (PFAPA) syndrome and other autoinflammatory periodic fever symptoms.[28] An ESR <50 mm/hr does not exclude Kawasaki disease but makes the diagnosis unlikely.[29] Immune globulin intravenous therapy causes some elevation of the ESR.[30,31]

Box 288.2

Effects of Conditions Other Than Infectious Diseases on the Erythrocyte Sedimentation Rate

Increase in Erythrocyte Sedimentation Rate

Noninflammatory or Unclear Mechanism

Anemias with normal red blood cell shape

Elevated nonfibrinogen proteins: M proteins, macroglobulins, red blood cell agglutinins

Immune globulin intravenous

Heparin therapy, heparin in sample (sodium citrate and ethylenediaminetetraacetic acid do not affect erythrocyte sedimentation rate)

Oral contraceptive agents

Obesity

Multiple myeloma

Renal cell carcinoma

Glomerulonephritis

Pregnancy

Hypothyroidism

Hypercholesterolemia

Chronic renal failure

Diabetes and nephropathy

Technical factors (e.g., tilting test tube just 3 degrees from vertical can accelerate ≤30 mm/hr)

Inflammatory or Presumed Inflammatory Mechanism

Hodgkin disease

Lymphoproliferative disorders

Other malignant diseases

Paraneoplastic syndromes

Collagen vascular disease

Autoimmune diseases

Autoinflammatory disorders

Rheumatic and other poststreptococcal syndromes

Myocardial infarction

Postpericardiotomy syndrome

Lymphocytic thyroiditis

Kawasaki disease

Serum sickness

Burn injury

Accidental and surgical trauma

Inflammatory bowel disease

Sinus histiocytosis with massive lymphadenopathy (Rosai-Dorfman disease)

Histiocytic necrotizing lymphadenitis (Kikuchi-Fujimoto disease)

Neutrophilic dermatosis (Sweet syndrome)

Benign hyperplastic lymphadenopathy (Castleman disease)

Decrease in Erythrocyte Sedimentation Rate

Morphologic abnormalities of red blood cells (e.g., sickle cells, spherocytes, anisocytes, poikilocytes)

Diffuse intravascular coagulation (e.g., associated with infection, hemophagocytic lymphohistiocytosis, macrophage activation syndrome)

Polycythemia

Leukemoid reaction

Dysfibrinoginemia, afibrinogenemia

Extreme elevation of serum bile salt concentration

Congestive heart failure

Valproic acid

Glucocorticoids

Low-molecular-weight dextran

Asparaginase

Cachexia

Technical factors (e.g., sample >2 hours old, non–room temperature sample after refrigeration)

Discordant results between the ESR and other markers of inflammation, particularly CRP, can be clues to infectious and noninfectious diseases. Low ESR and high CRP have been reported in Kawasaki disease[32] and in severe inflammatory bowel disease,[33] whereas high ESR with normal or mildly elevated CRP can be a clue to underlying autoimmune disease or chronic indolent infection.

Extreme Elevation of the Sedimentation Rate

Box 288.3 shows infectious and noninfectious conditions that should be considered especially when the ESR exceeds 100 mm/hr. Extreme elevation of the ESR is characteristic of certain noninfectious conditions. In children (unlike adults), however, infection still is a likely cause, accounting for 56% of cases in 1 study of 156 children[34]; miliary tuberculosis is notable among infectious diseases.[15] Collagen vascular, renal, and macrophage disorders and neoplastic disease rise among differential diagnoses. An extreme elevation of the ESR at the diagnosis of bacterial infection does not in itself indicate complicated disease or a guarded prognosis.

Box 288.3

Infections and Other Conditions Associated With Erythrocyte Sedimentation Rate >100 mm/hr

Infections

Miliary tuberculosis

Lymphadenitis or visceral infection caused by *Bartonella henselae*

Soft tissue or serosal infections caused by *Streptococcus pyogenes* or *Streptococcus pneumoniae*

Pyelonephritis

Bacterial arthritis

Soft tissue infections of the head and neck

Pelvic inflammatory disease

Ruptured appendicitis

Infective endocarditis

Other Conditions

Autoimmune diseases

Autoinflammatory disorders

Kawasaki disease

Postinfectious and rheumatic disorders

Erythema nodosum

Sarcoidosis

Malignant lymphoma

Acute leukemia

Neuroblastoma

Other malignant diseases, especially metastatic carcinoma

Renal disease and nephrotic syndrome

Multiple myeloma

Visceral inflammatory pseudotumor

Sweet syndrome

Hyper IgD syndrome/mevalonate kinase deficiency

Drug hypersensitivity

Low Erythrocyte Sedimentation Rate

Causes of a low ESR are shown in Box 288.2. In children with infectious diseases, an abnormally low ESR (e.g., <4 mm/hr) is most frequently a sign of disseminated intravascular coagulopathy and reflects low plasma fibrinogen concentration; elevated fibrinolytic markers (e.g., D-dimer) are expected. Administration of glucocorticoids and possibly high-dose (but not low-dose) salicylates and L-asparaginase lower the ESR,[35] as does performance of peritoneal dialysis or hemodialysis.[36] The ESR is not valueless in children with sickle cell disease; in 1 study, 72% of hospitalized children with an ESR >20 mm/hr had clinical infection (and 38% had vaso-occlusive crisis) compared with 23% with an ESR of ≤20 mm/hr, 74% of whom had vaso-occlusive crisis.[37,38]

C-Reactive Protein

Physiology and Measurement

The production of IL-6, and less so IL-1β, stimulates hepatocytes to produce CRP, a protein so named because of precipitation with C-polysaccharide of the pneumococcal cell wall. Although the liver is the main source of CRP, extrahepatic sites can directly produce smaller amounts, including macrophages, monocytes, lymphocytes, neurons, respiratory and renal epithelial cells, and smooth muscle cells. The CRP level increases within 4 to 6 hours of an inflammatory stimulus, doubles every 8 hours, peaks at levels 100 to 1000 times normal within 1 to 3 days, and then falls relatively rapidly (with a half-life of 19 hours) once the triggering stimulus ceases. Functional properties of CRP include stimulation of opsonization by binding bacteria and parasites, directly activating complement through the classic pathway modulating function of phagocytic cells, and augmentation cell-mediated cytotoxicity.[6,39–41] Nephelometric assays remain the most widely used techniques for measuring CRP; a value <1 mg/dL (10 mg/L) is considered "normal" for clinical predictive purposes. Normal range is variable by the test used. Modest longterm elevations (>0.3 mg/dL) using high-sensitivity CRP tests have been used as markers of increased risk of atherosclerosis.[10,42,43]

Compared with the ESR, CRP rises more rapidly, peaks earlier, and returns to normal levels more quickly when the stimulus abates. Factors that affect the ESR, such as anemia, polycythemia, protein levels, and RBC shape, do not affect CRP values. Any tissue injury, however, such as trauma, burn injury, ischemia, or infarction, can elicit production of CRP. Because CRP is degraded rapidly, serial determinations can provide additional information on progression of an insult or the effect of therapy.[23,44] Liver failure and certain rare inherited immunodeficiencies (e.g., nuclear factor-κB [NF-κB] pathway defects) can cause "falsely" low CRP levels in the presence of invasive bacterial or fungal infection.[45]

Clinical Usefulness

In general, CRP levels are elevated substantially (15–35 mg/dL) in bacterial infections with a tissue site of infection and only modestly (<2–4 mg/dL) in most acute viral infections; a value >10 mg/dL is more likely to be associated with bacterial infection, although infections with certain viruses (e.g., adenovirus, cytomegalovirus [CMV], influenza, measles, and mumps) can cause CRP levels >10 mg/dL.[7,35] Limitations in validating the accuracy of elevated CRP to predict serious bacterial infection (SBI) in neonates and infants with fever but without a clinical focus of infection include variable cutoff values used and the low incidence of SBI.[46–49] Pooled estimates in studies with cutoff values of 1 to 7 mg/dL showed sensitivity for SBI of 63% to 95% and specificity 40% to 91%,[47] and 6 studies, 3 of which used a cutoff value of 4 mg/dL, showed sensitivity of 77% and specificity of 79%.[48] In neonates, sensitivity for culture-proven early onset sepsis was only 39%.[49] Combined with other biomarkers such as IL-6, IL-8, and PCT, the diagnostic accuracy of CRP for early onset sepsis improves.[8,50] "Elevated" CRP can occur spontaneously in neonates in the first 48 hours of life (≤1 mg/dL),[49] in the 48 hours after injections of multiple vaccines (>1 mg/dL),[51] and 1 to 2 days following major surgical procedures (median peak, 2 mg/dL).[52] Benitz and colleagues[53] concluded that no currently available laboratory marker has predictive values exquisite enough to drive algorithms for management regarding early onset sepsis. CRP appears to be less sensitive than IL-8 or PCT for detecting SBI in oncologic patients with fever and neutropenia.[54–56]

CRP level has better predictive value for distinguishing bacterial infection when a tissue focus of infection is identified. A meta-analysis of 8 studies including 1230 children with pneumonia showed a positive predictive value (PPV) of CRP >4 mg/dL for bacterial pneumonia of 64%.[57] In 1 study CRP ≥2 mg/dL detected bacterial meningitis in patients despite negative Gram stain findings (sensitivity, 96%; specificity, 93%; negative predictive value [NPV], 99%).[58] In another study, CRP level >2 mg/dL was an independent risk factor for pyogenic arthritis (odds ratio, 14.5; 95% confidence interval [CI], 3.2–64.9) compared with toxic synovitis.[59]

Discordantly high CRP levels compared with other acute phase reactants (especially WBCs and ESR) have been noted, such as in Kawasaki disease,[32] focal bacterial infections (in 1 study 26% of cases had a WBC count <15,000/mm^3 and CRP ≥8 mg/dL),[60] Crohn disease,[61] neoplasms of the liver and reticuloendothelial system (e.g., lymphoma), Castleman disease, allograft rejection, and graft-versus-host disease.[44,62]

Sequential measurement of CRP is valuable as an assessment of therapeutic control of focal infections, including wound infections following spinal operations[63] and infective endocarditis,[64] and as a clue to ineffective therapy or complicated infection such as undrained abscess and tissue necrosis.[26,45,46] Serial CRP levels that increase or fail to decrease after 48 hours of therapy suggest treatment failure, a complication, or a noninfectious diagnosis.[46] A meta-analysis of CRP values following abdominal operations (using variable threshold values by surgical procedure) showed an 84% NPV for infectious complication when measured on postoperative day 4.[65] Serially measured normal CRP values have a better NPV for bacterial infection in certain clinical settings, including early onset neonatal sepsis[8,50,66] and fever without a source in infants and young children.[67–72] A CRP value of <2 to 3 mg/dL in an afebrile, clinically improving patient has been used as an adjunct marker for safe transition from parenteral to oral antibiotic therapy for patients with uncomplicated pediatric osteoarticular infections.[73]

Serial concomitant testing of both ESR and CRP during acute infection likely is not beneficial compared with CRP measurements alone.[74] In patients with suspected or known chronic autoimmune diseases, following both values may assist in differentiating disease progression from acute infection.

Procalcitonin

Physiology and Measurement

Biologic activities of PCT, the prohormone of calcitonin, include lowering serum calcium concentration by inhibition of bone resorption and signaling of bacterial invasion. In animal models, induction of bacterial infection or administration of endotoxin results in synthesis of PCT by virtually all tissues and organs that is detectable in serum within 2 to 4 hours, peaks at 12 to 48 hours, and has a half-life of 22 to 26 hours.[75,76] PCT does not have known direct inflammatory effects, but it is a potent amplifier of the proinflammatory cascade.[77] PCT levels generally are not increased in response to viral infections (possibly in part because of the inhibitory effect of interferon),[6,75,77] in systemic autoimmune disease, inflammatory bowel disease, or some arteritis syndromes. PCT levels can rise transiently in patients with severe trauma, burns, and extensive surgical procedures, as well as during T-lymphocyte antibody therapy and graft-versus-host disease.[7]

Normative values of PCT by age and differences in tests and cutoff points in clinical studies confound consensus interpretation of results. Based on highly sensitive research assays, the normal PCT level in uninfected adults is 0.003 to 0.033 ng/mL.[75] During the first 48 hours of life in healthy neonates, the upper limit of 95% CI increases from 0.7 ng/mL at birth to 20 ng/mL at 24 hours, declines to 2 ng/mL at 48 hours of age, and normalizes to <0.1 ng/mL after 72 hours.[8,49,78]

The first commercially available test for PCT was an immunoluminometric assay with lower limit of sensitivity of 0.5 ng/mL; this cutoff was used for many studies and may be insensitive to detect bacterial infection. A second-generation PCT assay (a time-resolved, cryptate-emission [TRACE] immunoassay) cleared by the Food and Drug Administration has a functional lower limit of sensitivity of 0.05 ng/mL.[75] Clinicians should be familiar with their locally offered test and reference ranges and should recognize that comparisons of PCT values across institutions or studies may not be appropriate.[76,77]

Clinical Studies

Serum PCT levels rise and fall more rapidly than CRP levels during onset and control of bacterial infections and appear to have modestly increased sensitivity, specificity, predictive values, and ROC curve. The usefulness of PCT determinations may be offset partially by limitations in determining cutpoints and lower specificity in some populations of interest.[7,49,75] Despite numerous studies, optimal clinical application of PCT measurements remain uncertain,[79] with multiple systematic reviews and meta-analyses yielding conflicting results.[55,56,67,68,80–83] A focused review of research from 2012 through 2016 highlights, by types of infections, the evidence and limitations of PCT-guided antimicrobial management.[84]

Usefulness of PCT levels in the first 48 to 72 hours of life is unclear because of wide variations in study and testing characteristics, as well as physiologic factors (i.e., PCT crosses the placenta, and the PCT level can be high in newborns following uncomplicated delivery).[8,78,85] Studies of the usefulness of PCT in evaluation of late onset neonatal sepsis and young infants with fever without a focus have had mixed results. In a prospective observational study of infants ≤90 days of age who had fever without a focus of infection, the median PCT level was 0.53 ng/mL for infants with SBI, 0.29 ng/mL for infants with recent immunizations without SBI, and 0.17 ng/mL for infants with neither.[86,87] The proposed PCT cutpoint of 0.12 ng/mL showed sensitivity of 96%, specificity of 23%, and NPV of 96%. Generalizability to other age groups has been questioned.[88] Using cutpoints of <0.5 ng/mL and ≥2 ng/mL, PCT appeared to have superior ROC performance compared with other biomarkers for SBI in infants <36 months of age with fever for <8 hours[89]; additional studies have affirmed this performance.[69,71,72,90] More recently, studies have used a PCT cutpoint of 0.3 ng/mL for detecting or excluding serious or invasive infection in young febrile infants and children,[91–93] with mixed results of utility.[70,94] In a 2015 prospective French study of febrile infants 7 to 91 days of age who were seen in a pediatric emergency department, the determined sensitivity and specificity, respectively, of PCT for bacteremia or meningitis were evaluated using different cutpoints: PCT >0.3 ng/mL (90% and 78%); PCT >0.5 ng/mL (85% and 85%); PCT >2 ng/mL (60% and 94%). When identification of urinary tract infection was included, the utility of PCT approximated that of CRP (ROC area under the curve, 0.81 and 0.83, respectively).[91] Beyond infancy, a PCT value >2 ng/mL may more consistently correlate with bacterial infection, thus predicting either sepsis or poor outcome in a variety of populations.[81,95,96]

An elevated PCT concentration has reported predictive value for discriminating bacterial infection in febrile neutropenic children with cancer,[56,82,97] febrile children with sickle cell disease,[98] diarrhea-associated hemolytic uremic syndrome,[99] bacterial causes of acute hepatic disease,[100] septicemia versus systemic inflammatory response syndrome,[6,7,81,92,96,101–104] postoperative infection following pediatric cardiac surgical procedures,[105,106] bacterial versus aseptic meningitis,[107] bacterial pneumonia,[108,109] central venous catheter infection in children,[110] severe Crohn disease (cutoff, 0.14 ng/mL),[111] and pyelonephritis.[112] For pyelonephritis, PCT can serve to predict renal scarring.[112,113] PCT can be useful in discriminating bacterial infection in febrile adults with systemic autoimmune diseases.[114,115] In a systematic review of patients with systemic lupus erythematosus, a cutpoint of >0.5 ng/mL was optimally sensitive and specific.[83]

Pooling data to determine clinical guidelines for widespread use of PCT to initiate or withhold therapy has proved difficult. Two systematic reviews and meta-analyses demonstrated contradictory results: 1 report concluded that PCT was superior to CRP and WBC count for most clinical situations,[67] whereas the other concluded that PCT is inferior to current clinical predictive rules for identifying young febrile infants at risk for SBI.[80]

A multicenter noninferiority randomized trial of use of a PCT algorithm as a decision rule to initiate and discontinue antibiotics for community-acquired pneumonia in adults (antibiotics discouraged if PCT <0.25 ng/mL and encouraged if PCT >0.5 ng/mL) showed that application of the rule was associated with similar clinical outcome and reduced antibiotic exposure and adverse events[116]; the added value of PCT was questioned subsequently.[117,118] In a study of similar strategy to limit empiric therapy in children <36 months of age who had fever without a focus, the use of a PCT cutpoint of 0.5 ng/mL would have resulted in a 24% increase in antibiotic use in patients without a subsequent diagnosis of SBI.[94] In 2013, a European expert panel concluded that sufficient evidence exists to discontinue antibiotics safely based on PCT values alone for only 1 subgroup of adult patients: nonimmunocompromised patients in the intensive care unit who have suspected respiratory tract infection (i.e., when PCT is <0.25 ng/mL or decreased by 80%–90% at day 3).[119] Although similar PCT strategies to initiate or discontinue antibiotics have been studied in children, data are insufficient for safe support of such application routinely in any clinical setting.[102,120]

Other Acute Phase Proteins and Cytokines

Cytokines (e.g., IL-6, IL-8, IL-10), chemokines (e.g., TNF-α), acute phase proteins, and receptor molecules are being studied in humans.[6–8,103,121,122] Although clinical applications for detection of early points of infection are encouraging (e.g., sensitivity and ROC analyses), many biomarker responses are short-lived events, and no single mediator is likely to have broad application clinically.[6,49,52,54] Stratifying the utility of biomarkers related to timing of measurement, use for diagnosis versus prognosis, for NPV versus PPV, or for patient groups versus disease states can help to clarify the most valid roles of these biomarkers.[6,8,77,122]

Pediatric studies suggest that peripheral blood IL-6 and IL-8 levels may be the most promising for early identification of sepsis in several specific patient populations. Although IL-6 (with cutoff values of 20−50 pg/mL) has high sensitivity for identifying early onset sepsis in newborns, its half-life is very short, and timely measurement is challenging.[6,8,121,122]

IL-8 has demonstrated potential as an indicator of early gut ischemia and predictor of death in necrotizing enterocolitis,[8,121,123,124] and it may be more sensitive than CRP for detecting bloodstream infection in oncologic patients with fever and neutropenia.[55]

Ferritin is a highly conserved, ubiquitous intracellular protein, control of which depends on multiple genes, regulatory messenger RNA structures, signaling pathways, and protein catalysts. Ferritin tightly controls iron and oxygen chemistry. Expression is upregulated by proinflammatory cytokines; expression also is regulated by thyroid hormone, insulin, insulin growth factors, hypoxia and ischemia, and hyperoxia (nitric oxide). Immunologic activities include binding to T lymphocytes, suppression of delayed-type hypersensitivity and B-lymphocyte antibody production, and regulation of granulomonocytopoiesis. Normal serum ferritin concentrations in men is <400 μg/L (<400 ng/mL) and in women is <150 μg/L.

Serum ferritin levels are markers of iron deficiency (low) and iron intoxication or overload states (high). Levels also are elevated in inflammation, infection, and hypoxia and ischemia. Clinical interest has escalated because of the usefulness of ferritin as a criterion (serum level >500 μg/L) for hemophagocytic lymphohistiocystosis and macrophage activation syndrome, in which peak levels frequently exceed 10,000 μg/L.[125,126] Moderately elevated ferritin levels (>500 μg/L and even >1000 μg/L) also occur in severe sepsis,[127] dengue hemorrhagic fever, lymphoma, systemic lupus erythematosus, and other autoimmune and autoinflammatory conditions.[128,129]

Other acute phase proteins under investigation in pediatric populations include hepcidin,[130,131] presepsin (a soluble lymphocyte CD14 subtype),[6,121] serum and fecal calprotectin,[132] and serum amyloid A.[6,8,121] Receptor molecules also may be promising biomarkers of sepsis, including soluble triggering receptor expressed on myeloid cell (sTREM),[6,122] urokinase plasminogen activator receptor (uPAR),[6,8] neutrophil CD64 (nCD64),[6,8,122,133] and others.[103] At a cutpoint index value of 2.38, nCD64 has been found to predict early onset sepsis in neonates with 100% sensitivity, 68%

specificity, and 100% NPV.[8,133] Further studies for optimal testing and clinical application are needed.

Hemoglobin

Erythrocytosis and Hemoconcentration

Erythrocytosis (polycythemia) secondary to increased erythropoietin production in response to arterial hypoxemia can provide a clue to cryptogenic bronchiectasis. Hemoconcentration is defined as hematocrit level >44% in men and >40% in women. Probably primarily a result of plasma leakage, hemoconcentration is characteristic of severe or toxic infections such as hantavirus pulmonary syndrome, dengue hemorrhagic fever, clostridial toxic shock, and necrotizing pancreatitis, and it generally portends a poor outcome.[134–137] Methemoglobulinemia is well described in young infants with diarrheal disease or urinary tract infection possibly due at least partially to absorption of nitrites produced by enteric organisms.[138]

Anemia in Chronic Infection

The anemia of chronic disease likely is driven by cytokines and reticuloendothelial cells that induce pathologic changes in iron homeostasis, impaired erythropoiesis, blunted erythropoietin response, and decrease in RBC lifespan.[139] Anemia is mildly to moderately severe, reflecting extent and duration of infection, and is associated with reticulocytopenia. Erythrocyte mean corpuscular hemoglobin and volume usually are normal. The serum ferritin value frequently is increased. An iron deficient type of erythropoiesis (low serum iron and increased erythrocyte protoporphyrin concentrations) results despite normal or increased iron stores.

Anemia of chronic disease is expected in clinical tuberculosis, subacute infective endocarditis, human immunodeficiency virus (HIV) infection, hepatitis C, malaria, and chronic osteomyelitis. Successful treatment of the infection is the only effective therapy. Noninfectious inflammatory conditions such as autoimmune disorders, malignant solid tumors, and autoinflammatory diseases (e.g., inflammatory bowel disease) typically are associated with anemia of chronic disease, and in some cases anemia responds to the administration of recombinant erythropoietin. Anemia can be a clue to the diagnosis of Crohn disease in children without overt abdominal symptoms who are being evaluated for fever of unknown origin. RBC indices also can reflect true iron deficiency anemia from gastrointestinal blood loss in these patients. Hookworm infestation is another cause of occult blood loss and iron deficiency anemia.

Anemia in Acute Infection

Mild, readily reversible, normocytic anemia (hemoglobin, 9–11 mg/dL) is not uncommon in patients with minor bacterial and viral infections and is characterized by mild hemolysis and diminished RBC production. A profoundly decreased total and free serum iron concentration (e.g., transferrin saturation <10%) is an expected acute response to infection or inflammation; measurement during acute infection is inappropriate and frequently leads to incorrect conclusions and therapy.

Approximately 50% of children with acute SBIs (meningitis, pneumonia, arthritis) have anemia (hemoglobin <11 g/dL) at the time of hospitalization. Moderate to severe acute hemolysis can occur in exotoxin-mediated syndromes secondary to *Staphylococcus aureus* and *Streptococcus pyogenes* or in septicemia caused by endotoxin-producing enteric bacteria or *Neisseria meningitidis*. Hemolysis occurs in patients with disseminated intravascular coagulopathy associated with severe infection caused by a variety of bacteria, rickettsiae, fungi, viruses, and protozoa; expected associated findings are burred RBCs, elevated serum lactate dehydrogenase and unconjugated bilirubin levels, and a reduced haptoglobin level. Severe acute hemolysis and thrombosis leading to hemolytic uremic syndrome is an increasingly reported complication of pneumococcal infection in children, especially complicated pneumonia.[140,141] *Mycoplasma pneumoniae*, Epstein-Barr virus (EBV), and cytomegalovirus (CMV) can produce immune-mediated hemolytic anemia, and *Vibrio cholerae* can elicit nonimmune acute hemolytic anemia. *Plasmodium falciparum* malaria and clostridial septicemia classically are associated with marked intravascular hemolysis and profound anemia. Severe and sometimes fatal hemolysis, which probably is immune mediated, has been associated with initiation of ceftriaxone therapy in several children with a variety of underlying conditions who were previously exposed to ceftriaxone.[142,143]

Transient erythroblastopenia is an acute phase response to many infections and usually is of no or minor consequence in previously healthy children. Occasionally erythroblastopenia can be severe and can be associated with autoantibodies against erythroid progenitors or possibly erythropoietin. Viruses causing protracted infections (e.g., EBV, CMV) in immunocompetent children and especially in immunocompromised children, as well as those with HIV infection, can result in varying degrees of anemia. Acute human parvovirus B19 infection consistently causes transient reticulocytopenia with little consequence, except in people with shortened RBC survival in whom aplastic crisis occurs, in intrauterine life when interrupted erythropoiesis can cause hydrops fetalis, or in immunosuppressed people in whom protracted infection leads to significant anemia or pancytopenia.[144,145] Hepatitis viruses frequently suppress bone marrow during acute infection that rarely can result in permanent aplastic anemia. Hemophagocytic syndromes leading to pancytopenia can be triggered by many infections, especially those caused by herpesviruses, RBCs, and other intracellular pathogens, such as *Babesia*, parvovirus B19, *Brucella, Salmonella,* and *Histoplasma*.[146] In boys with X-linked lymphoproliferative disorder, EBV infection is associated with hepatitis and aplastic anemia, with high mortality rates.

Leukocytes

Circulating leukocytes are produced by the bone marrow in response to specific growth factors, and normal ranges vary with age (Table 288.1).[147] Leukocytosis is an increase in the total WBC count higher than the 95% confidence limits of the mean for age (i.e., approximately >11,000/mm^3 for adults, >13,000–15,000/mm^3 for children 4–16 years of age, and >20,000/mm^3 for infants 1–4 weeks of age). Leukocytosis is less meaningful clinically than are terms that describe the predominant type of leukocyte that is increased.

TABLE 288.1

Approximate Normal Leukocyte Counts in Children[a]

	Total Leukocytes		Neutrophils			Lymphocytes			Monocytes		Eosinophils	
Age	**Mean**	**Range**	**Mean**	**Range**	**Percent (%)**	**Mean**	**Range**	**Percent (%)**	**Mean**	**Percent (%)**	**Mean**	**Perce**

Neutrophilia

Neutrophils exist in 3 major anatomic spaces; these cells move unidirectionally from bone marrow, to peripheral blood, to extravascular spaces. Peripheral blood neutrophils are divided equally between the circulating pool and the marginated pool (where they are attached to or roll along the walls of capillaries or postcapillary venules). The number of neutrophils at each site can be regulated independently and influenced by various colony-stimulating factors (granulocyte colony-stimulating factor [G-CSF] and granulocyte-macrophage CSF [GM-CSF]). In an acute inflammatory response, neutrophils are released from the marrow granulocyte reserve (containing 10–15 times as many neutrophils as normally are present in circulating blood) into the bloodstream and migrate by margination and diapedesis to extravascular foci of tissue injury. In the bone marrow, CSFs act on progenitor cells to increase mitosis and expand the storage pool. Segmented neutrophils are released preferentially, but as release accelerates, less maturely segmented band cells and a few metamyelocytes also can be released and produce a “shift to the left.” Neutrophilia also can occur from movement of neutrophil pools in response to a variety of noninfectious stimuli. Endogenous or administered glucocorticoids and epinephrine cause demargination of neutrophils in the bloodstream, and glucocorticoids increase the half-life of neutrophils.[35,148] Immature forms are not expected. Tissue damage or necrosis such as from accidental or surgical trauma, fracture, burn injury, hypoxia, stress, lactic acidosis and ketoacidosis, acute hemolysis or hemorrhage, and systemic autoimmune and inflammatory conditions can induce complex acute phase responses, mitotic activation in marrow, and redistribution of neutrophils causing neutrophilia, sometimes with a modest left shift.

Bacterial and fungal cell wall products, exotoxins, and endotoxins are potent stimuli of the acute inflammatory response of neutrophils. Progressive elevation of the WBC count higher than 15,000/mm^3 with neutrophil predominance heightens suspicion of bacterial infection, but discrimination between viral and bacterial respiratory tract infections is not precise.[14] In 1 study of 121 children with pneumonia, the mean WBC count was 18,000/mm^3 for *Streptococcus pneumoniae,* 17,000/mm^3 for adenovirus, and 9000/mm^3 for *M. pneumoniae* causes.[148] In a retrospective case-control study of 69 children 2 to 24 months of age who were evaluated in an emergency department for a febrile illness, the rate of SBI was only 25% in those children with WBC counts >25,000/mm.[149] Absolute neutrophil count (ANC) rather than total WBC count and duration of fever are better predictors of SBI in febrile infants.[150,151]

SBIs do not always induce leukocytosis; exotoxin- and endotoxin-producing organisms such as *S. aureus, Haemophilus influenzae* type b, and *Salmonella* infections are most noteworthy. In 1 study, only 50% of the children hospitalized with proven bacterial infection had a WBC count >15,000/mm.[3,148] In a prospective observational study performed in 856 neonates who were born at >35 weeks' gestation and had been exposed to suspected chorioamnionitis, single or serial neutrophil values did not assist in the diagnosis of early onset infection.[152] In an analysis of administrative data from >166,000 neonates, most infants with proven SBI had normal total WBC counts (60%; 5000–19,000/mm^3) and ANC (87%; >1500/mm^3). Low

WBC count (<5000/mm^3 and <1000/mm^3), low ANC, and high immature-to total neutrophil ratio were associated with increasing odds of infection. No single or combination of WBC values could reliably exclude SBI.[153]

Extreme Elevations of Neutrophils and Leukemoid Reaction

Any cell type can be involved in a leukemoid reaction, so named because of the simulation of findings in leukemia. A myeloid leukemoid reaction is defined as a peripheral WBC count >50,000/mm^3 or a differential cell count with >5% immature myeloid cells capable of division (myeloblasts, promyelocytes, and myelocytes). The former type is more frequently encountered in children with infectious diseases. Box 288.4 lists causes of a myeloid leukemoid reaction. Severe bacterial infections are associated with this reaction most frequently. Viral infections do not cause a myeloid leukemoid reaction. Disseminated fungal infections can cause mild to profound neutrophilia (e.g., with thrombocytopenia in neonates with candidemia and eosinophilia in disseminated cryptococcosis) or neutropenia (e.g., with thrombocytopenia in disseminated histoplasmosis). Shigellosis, particularly *Shigella dysenteriae* infection, is associated with a leukemoid reaction more frequently in children younger than 4 years of age and characteristically has predominantly immature neutrophils as findings, but lymphocyte counts can be elevated as well. Leukemoid reactions result from *Clostridium difficile* colitis with toxin-hyperproducing strains and severe disease,[154] as well as from *Clostridium sordellii* in patients with myonecrosis and septicemia.[155] Malignant diseases, especially carcinomas, can express certain CSF genes that stimulate neutrophilia inappropriately and sometimes cause paraneoplastic syndromes. Myelogenous leukemia, which is most frequently associated with a leukemoid reaction, usually is distinguished by a disproportionately high number of blast forms compared with bands and metamyelocytes, as well as by the presence of anemia, thrombocytopenia, eosinophilia, and basophilia. Young infants with trisomy 21 can have a leukemoid reaction, which usually is transient but can evolve into a leukemic state.[155] Prenatal administration of betamethasone can cause neonatal leukemoid reaction.

Box 288.4

Causes of Myeloid Leukemoid Reaction in Children[a]

Infectious Causes

Septicemia

Severe acute necrotizing focal infection

Shigellosis

Salmonellosis

Clostridium difficile colitis

Cryptogenic abscess

Miliary or acute necrotizing tuberculosis

Disseminated candidiasis, cryptococcosis

Malaria[b]

Meningococcemia[b]

Infection in children with leukocyte adhesion defect

Bubonic plague

Diphtheria

Noninfectious Causes

Severe acute hemolysis or hemorrhage

Severe tissue ischemia

Bone marrow recovery from severe drug-induced suppression

Multiple fractures

Diabetic ketoacidosis

Collagen vascular and autoimmune diseases

Sarcoidosis

Kawasaki disease (young infants especially)

Carcinomas producing colony-stimulating factors

Acute leukemia, malignant lymphoma with marrow infiltration

Paraneoplastic syndrome

Chronic myeloproliferative disorders

Neonate with trisomy 21

Antenatal administration of betamethasone

Osteopetrosis

Gaucher disease

Postsplenectomy status

Severe burns

Mercury poisoning

---

[a] Total white blood cell count >50,000/mm^3 (with predominantly neutrophils) or >5% myeloblasts, promyelocytes, or myelocytes in peripheral blood.

[b] Extreme left shift type of leukemoid reaction, or with neutropenia.

Neutropenia

Neutropenia is defined as a peripheral blood neutrophil count lower than the 95% confidence limit for age (see Table 288.1), usually an ANC <1500/mm^3 in children older than 1 month of age.[147] Undue susceptibility to infection because of neutropenia correlates best with an ANC <500/mm^3. Neutropenia related to infectious diseases can be caused by the infectious agent itself, infection-triggered hemophagocytosis, postinfectious immune mechanisms, or marrow suppression related to antibiotics or other drugs.[156] During severe infection, margination and diapedesis of neutrophils into tissues are increased at the expense of circulating cells in peripheral blood, thus leading to neutropenia. Bands and metamyelocytes are pushed from marrow peripherally and can equal or outnumber mature neutrophils; cells are vacuolated, with toxic granulations and Döhle bodies. Bone marrow findings can be confusing, with myeloid hyperplasia and "maturation arrest" at the promyelocyte stage. Neutropenia is a poor prognostic sign in rapidly progressive bacterial infections.

Pseudomonas septicemia in previously healthy children, a condition frequently associated with excessive exposure to water (whirlpool, bathing, wet toweling for antipyresis), can cause profound neutropenia with an extreme shift to the left,[157] occasionally with a myeloid leukemoid reaction simulating promyelocytic leukemia.[158] These findings initially can cause confusion because *Pseudomonas* septicemia also complicates congenital and acquired neutropenic states. Toxin-producing bacteria, such as *S. aureus, S. pyogenes,* and enteric gram-negative bacilli (*Escherichia coli, Salmonella, Brucella, Shigella*), have a propensity to cause a disproportionate left shift, frequently with immature neutrophils exceeding mature cells, and a low to normal total neutrophil count; such findings do not indicate a poor prognosis or even bacteremia. Neutropenia or neutrophilia can occur in disseminated tuberculosis and histoplasmosis, as well as in Rocky Mountain spotted fever; when the WBC count is <10,000/mm^3 in patients with Rocky Mountain spotted fever, bands frequently exceed mature forms.[159] Leukopenia occurs in 60% to 74% of cases of ehrlichiosis and in 50% of cases of anaplasmosis with a reduction in mononuclear and polymorphonuclear cells; organisms can be visualized in leukocytes.[160,161]

Mild neutropenia frequently accompanies systemic viral infections. Neutropenia and thrombocytopenia can be clues to subclinical CMV infection in organ transplant recipients,[162] symptomatic primary infection with HIV, or acquired immunodeficiency syndrome (AIDS).[163] In a report from Israel, many children with bacterial and viral infections had aggregated leukocytes that led to false reading of leukopenia by automated cell analyzers.[164]

Left Shift of Neutrophils, Immature Neutrophils

Use of the ratio of immature to total neutrophils in neonates younger than 7 days of age to predict bacterial infection has been reported extensively, with disparate results. In a large study, a band neutrophil–to–total neutrophil ratio ≥0.2 had sensitivity and NPV for bacterial infection exceeding 95%.[49] Adenovirus infection,[165] influenza A,[166] disseminated herpes simplex,[167] and other viral infections can be associated with increased absolute band count simulating bacterial sepsis.[167] In viral infections and in malaria when immature neutrophils are seen in peripheral blood, the total ANC is <10,000/mm^3 in almost 90% of cases.[167]

Lymphocytes and Lymphocytosis

Although T and B lymphocytes replicate in multiple anatomic sites (including the lymph nodes, spleen, and bone marrow) and are capable of leaving and re-entering a given compartment, lymphocytes in peripheral blood are tightly regulated, with T lymphocytes predominating and numbers predictable by age (see Table 288.1). Mean counts decrease with age after a peak of 7300/mm^3 (61% of leukocytes) at 6 months of age. Lymphocytosis is present when the count exceeds the 95% confidence limits for age; by definition, a lymphocytic leukemoid reaction requires the presence of immature forms in peripheral blood. Causes of lymphocytosis are shown in Box 288.5.

Box 288.5

Causes of Abnormal Lymphocyte Counts in Children

Lymphocytosis

Infectious

Infection with *Bordetella pertussis,* Epstein-Barr virus, cytomegalovirus, hepatitis viruses, other common viruses, *Toxoplasma;* chronic controlled bacterial infections (e.g., *Treponema, Brucella, Mycobacterium*); recovery from bacterial infections; *Rickettsia* infection

Noninfectious

Lymphocytic leukemias, thyrotoxicosis

Lymphopenia

Infectious

Acute and chronic viral infection (including human immunodeficiency virus), acute bacterial infection, widespread granulomatous infection (e.g., untreated *Mycobacterium, Cryptococcus, Histoplasma*), malaria

Noninfectious

Protein-calorie malnutrition, radiation or immunosuppressive therapy, monoclonal antibody and anticytokine therapy, congenital immunodeficiency, untreated Hodgkin lymphoma, trauma, stress, glucocorticoids, antibody-mediated destruction, protein-losing enteropathy, chronic right heart failure, lymphangiectasias, thoracic duct interruption

Bordetella pertussis infection is the only acute bacterial infection typically associated with lymphocytosis. Lymphocytosis results from blockade by pertussis toxin of the normal migration of lymphocytes out of the bloodstream, and the degree is predictive of the severity of illness and fatal outcome (mean leukocyte count in fatal vs. nonfatal cases in young infants, 94,000 vs. 18,000/mm^3).[168–170] Chronic bacterial and bacterial granulomatous infections can cause sustained, modest lymphocytosis.

Although many viral infections cause mild transient lymphocytosis, mononucleosis syndromes related to EBV or CMV, as well as Kikuchi disease, induce sustained lymphocytosis. The atypical lymphocytes in viral infections reflect active proliferation of T lymphocytes; these lymphocytes are large and have distinctive morphologic features. Profound atypical lymphocytosis (>50% of lymphocytes) occurs with EBV infection almost exclusively. More modest atypical lymphocytosis can occur in infection with CMV (including postperfusion syndrome), HIV (acute), hepatitis A or B viruses, adenovirus, and *Toxoplasma gondii* (congenital and acute), as well as in leukemia and lymphoma. Mild atypical lymphocytosis (usually <10%) occurs in drug reactions, serum sickness, infections with other viruses (rubella, rubeola, human herpesvirus 6, herpes simplex, varicella zoster), and infection with certain bacteria (*M. tuberculosis, Treponema pallidum, Salmonella*). Atypical lymphocytosis is described in patients with malaria, and it is a consistent finding in babesiosis (usually <10%) despite normal or mildly depressed leukocyte count.[171] Multiple infectious, hematologic, and immunologic causes of neutropenia, as well as Addison disease, lead to relative lymphocytosis without absolute lymphocytosis.

Lymphopenia

Lymphopenia, defined as a peripheral blood lymphocyte count <1500/mm^3 (or <2000 in children < 6 years of age), has multiple causes (e.g., decreased production, increased loss or destruction, alteration in compartmentalization). Protein-calorie malnutrition is the most common cause of reduced-production lymphopenia worldwide. Viruses (e.g., HIV, rubeola, polioviruses, varicella-zoster) can infect lymphocytes and cause destruction, transiently decreased production, or trafficking from the blood compartment. Autoimmune disorders and widespread granulomatous infection, especially tuberculosis, cause lymphopenia, probably by decreased production and redistribution.[15] Acute bacterial infection and infection with *Rickettsia* and *Ehrlichia* cause lymphopenia as part of redistribution during the acute phase response.

Monocytes and Monocytosis

Absolute deficiency of the highly conserved monocyte-macrophage cell line probably is incompatible with life. Monocytes present antigens to lymphocytes, mediate cellular cytotoxicity, and regulate immune and hematopoietic responses by producing interleukins, interferon, TNF-α, and G-CSF. Stromal cells (e.g., fibroblasts and endothelial cells) produce GM-CSF during inflammation and M-CSF constitutively, which in turn stimulate growth and differentiation of mononuclear phagocytes. These phagocytes are especially effective in killing obligate intracellular parasites such as fungi, viruses, rickettsia, protozoa, and certain bacteria and participate substantially in all types of granulomatous inflammation. Monocytosis is defined as a peripheral blood monocyte count >800/mm^3 in children or >500/mm^3 in adults. A monocytic leukemoid reaction is defined as a monocyte count >30% of a WBC count that is >30,000/mm^3.

Monocytosis has varied causes (Box 288.6). Monocytosis usually precedes recovery from neutropenia, and mild monocytosis is common in recovery from acute bacterial and viral illnesses. Monocytosis (average of 15% of the leukocyte count) is a hallmark of symptomatic congenital syphilis,[172] a frequent finding in miliary tuberculosis and congenital toxoplasmosis, and a variable finding in listeriosis (in which neutrophilia is more common except in neonates) and malaria. Premature infants can have monocytosis in the range of 2000 to 7000 cells/mm^3 as a reflection of an immature physiologic response to a variety of drugs or infusions of blood and albumin.[173] Several hematologic malignant diseases and chronic inflammatory states also are associated with peripheral blood monocytosis. In malignant histiocytosis, abnormal mononuclear phagocytes can be seen in the peripheral blood, along with neutropenia or neutrophilia.

Box 288.6

Causes of Monocytosis in Children

Infectious Causes

Recovery from acute infections

Bacterial endocarditis

Protozoal infections

Fungal infections

Salmonella enteric fever

Varicella and herpes zoster

Cytomegalovirus infection

Mycobacterium tuberculosis infection

Brucella species infection

Listeria monocytogenes infection

Treponema pallidum infection

Rickettsia rickettsiae infection

Noninfectious Causes

Hodgkin disease and non-Hodgkin lymphoma

Preleukemia

Myelomonocytic and myelogenous leukemia

Myeloproliferative disorders

Carcinomas

Collagen vascular disorders

Sarcoidosis

Inflammatory bowel disease

Cirrhosis

Drug reaction

Congenital and acquired neutropenia

Major depression

Recovery from marrow suppression

Postsplenectomy status

Eosinophils and Eosinophilia

Eosinophils are produced from progenitor cells in the bone marrow, largely under the influence of IL-5, IL-3, and GM-CSF. IL-5 promotes proliferation, maturation, and survival of eosinophils and facilitates chemotaxis into tissues.[174–176] Increased levels of IL-5 are found in patients with parasitic infections and other hypereosinophilic syndromes. In parasitic infection, eosinophils exert antibody-dependent (immunoglobulin G [IgG]- or IgE-assisted) cellular cytotoxicity and may play a role in the afferent upregulating arm of the immune response through antigen presentation and cytokine secretion. In addition, eosinophils play an immune-modulating role of potentially toxic mast cell degranulation in hypersensitivity reactions.

Eosinophils are predominantly tissue-based cells that spend only 1 to 2 days of their approximately 4-week lifespan in peripheral blood; the tissue-to-blood ratio is at least 100 : 1. Mature eosinophils are found most prominently in the skin and epithelial lining of the respiratory and gastrointestinal tracts. Inflammatory fluids and tissue exudates (e.g., lung and pleural fluid, cerebrospinal fluid) can be predominantly eosinophilic, are always pathologic, and have unique differential diagnoses. The normal mean peripheral blood eosinophil count in the first week of life is $500/\text{mm}^3$ and falls during the first 6 years to the adult mean of $200/\text{mm}^3$ (normally 2%–3% of WBCs). Eosinopenia results from adrenocortical hyperfunction and administration of corticosteroids and is part of the acute phase response. Eosinophilia (>500 cells/mm^3) can be classified etiologically as primary (hematologic malignant diseases and mastocytosis), secondary (allergy, adrenal insufficiency, medications, autoimmune conditions and infections), or idiopathic.[177] Hypereosinophilic syndrome is defined as an eosinophil count $>1500/\text{mm}^3$ for >6 months that leads to end-organ damage from infiltration of the heart, lungs, skin, or nerve tissue. Most cases of hypereosinophilic syndrome are idiopathic; a subset has defined molecular bases and is amenable to specific anti–IL-5 treatment.[176–182]

Table 288.2 delineates infectious and noninfectious conditions associated with mild, moderate, and extreme eosinophilia. Mild eosinophilia (≤ 1500 cells/mm^3) is common and occurs in the recovery phase of bacterial or viral illness, in response to drugs (usually in the absence of hypersensitivity symptoms), or as a manifestation of any type of atopic disease. Parasites are the most common causes of eosinophilia worldwide, and they can induce extreme eosinophilia (>5000 cells/mm^3) or an eosinophilic leukemoid reaction (>30% eosinophils with a WBC count >30,000/mm^3). With the exception of helminthic infections, secondary causes of eosinophilia rarely produce an absolute eosinophil count >1500 cells/mm^3.[183] The degree of peripheral eosinophilia in parasitosis usually is proportional to the extent of tissue invasion and is a dynamic process related to the life cycle of the parasite.[183,184] Eosinophilia can occur in the following situations: in the pulmonary migratory phase that precedes gastrointestinal localization by weeks to months, such as with *Ascaris lumbricoides* and *Trichuris trichiura;* in the sustained, highly inflammatory tissue phase, such as with *Trichinella spiralis, Toxocara canis,* and *Toxocara cati;* in the sustained, low-grade inflammatory state, such as with *Schistosoma, Strongyloides, Necator,* and filariae; during episodic tissue movement, such as with *Loa loa, Dracunculus,* and *Gnathostoma;* or after disruption of cysts or parasitic death, such as with *Echinococcus* and *Taenia solium* (cysticercosis).[184] *Strongyloides* hyperinfection syndrome usually is not associated with eosinophilia. *Enterobius vermicularis* (pinworms) can cause eosinophilia with counts <1000/mm^3. Protozoal infections (e.g., giardiasis, malaria, amebiasis, cryptosporidiosis) are not characteristically associated with eosinophilia, even though some degree of tissue invasion can occur. *Cystoisospora belli* can be an exception.[185] Adrenal insufficiency, especially resulting from infection with *Histoplasma, Cryptococcus,* CMV, or *Mycobacterium* and from opportunistic infection in compromised hosts, also causes infection-associated eosinophilia.

TABLE 288.2

Causes of Eosinophilia in Children

	Elevation of Peripheral Blood Eosinophil Count		
Conditions	**Mild (500–1500 Cells/mm^3)**	**Moderate (1500–5000 Cells/mm^3)**	**Extreme (>5000 Cells/mm^3)**
COMMON INFECTIOUS CAUSES			

Recovery from bacterial, viral infection	+++	+	
Ascaris lumbricoides (migratory)[a]	++	++	++

Fasciitis-panniculitis syndromes (Shulman disease)	+	+	
DRESS syndrome	+++	+	

[a] Eosinophilia-inducing parasitic infections that can be acquired in the United States.

+++, frequently seen in infection or condition; ++, not infrequently seen; +, occasionally seen or cases reported; DRESS, drug reaction with eosinophilia and systemic symptoms.

The life cycle of the parasite, as well as geography, dietary habits, and host factors are important when considering serologic or microscopic studies to evaluate children with eosinophilia. The prevalence of parasitic infections in new immigrants with eosinophilia ranges from 70% to 95%, compared with 14% to 40% in travelers.[183–187] Exposure greatly affects the likelihood of a parasitic cause of eosinophilia. Travelers who make short visits to urban areas and who adhere to protective dietary measures have low risk. A high-risk history includes the following: ingestion of carnivores *(Trichinella)*; ingestion of raw vegetables, unpeeled fruits, or unpurified water (helminths); ingestion of seafood in Southwest Asia (gastrointestinal, liver, and lung parasites); and swimming in freshwater in endemic areas *(Schistosoma)*.[183] Physical examination and identification of organ systems involved guide specific diagnostic evaluations. Asymptomatic eosinophilia is neither a highly sensitive nor a specific marker for parasitic disease.[184,187] The Centers for Disease Control and Prevention (CDC) has frequently updated online domestic guidelines for postarrival screening and presumptive treatment for refugees based on predeparture management, with recommendations for further screening as appropriate. The CDC recommends that all refugees receive predeparture single-dose albendazole therapy, as well as a screening complete blood count with a differential WBC. Given the increased risk for *Schistosoma* spp. infection, the CDC also recommends predeparture treatment with ivermectin for African, Asian, and Middle Eastern refugees from non–*L. loa* endemic areas and additional treatment with praziquantel for sub-Saharan African refugees because of the increased risk for *Strongyloides* infection. For immigrants who lack documentation of predeparture treatment, serologic testing should be performed for *Strongyloides, Schistosoma* (with urine for *S. haematobium* ova, if indicated), and *L. loa*, as appropriate per guidelines.[188]

The differential diagnosis of asymptomatic eosinophilia with negative results of stool evaluation is limited. Recommendations include serologic testing for *Strongyloides* and *Schistosoma* species when the absolute eosinophil count exceeds 400 cells/mm^3; in a pediatric refugee study, the PPV of an absolute eosinophil count >400 cells/mm^3 for confirming either pathogen was only 58%, and the NPV was only 75%.[187]

Fungal infections usually do not elicit eosinophilia, with noteworthy exceptions. *Cryptococcus neoformans* can induce intense eosinophilia in the rare case of a previously healthy young child with disseminated disease. Pulmonary infiltrate with eosinophilia syndromes comprise a group of heterogeneous disorders characterized by eosinophilic infiltration of the lung parenchyma. Eosinophilia in the peripheral blood and systemic symptoms typically but not invariably are present. Parasite-induced pulmonary infiltrate with eosinophilia is the most common of these disorders in children.[189] Wiskott-Aldrich syndrome, combined immunodeficiency, hyper-IgE syndrome,[190] graft-versus-host disease,[191] and renal and hepatic allograft organ rejection[192] are associated with eosinophilia, as are malignant diseases (lymphomas, leukemia) and preleukemic states.[193] Eosinophilia can occur in the early stage of HIV infection and in EBV-related lymphoma in AIDS.[194] Organ-specific eosinophilic inflammatory diseases such as eosinophilic gastrointestinal disorders, granuloma of bone, and meningoencephalitis (related to ventricular shunt material, shunt malfunction, vancomycin instillation, bacterial or parasitic infection) do not characteristically cause peripheral blood eosinophilia, but mild elevations can occur, especially in young children.[195–199] In very prematurely born neonates, eosinophilia (count >1000/mm^3) has been associated with an anabolic state (as well as L-tryptophan exposure), but septicemia also occasionally induces eosinophilia rather than neutrophilia.[200,201] Other causes of eosinophilia are shown in Table 288.2.[200–205] Drug reaction with eosinophilia and systemic symptoms (DRESS) is a serious multisystem disorder of unclear pathogenesis associated predominantly with administration of aromatic anticonvulsant agents and sulfonamides.[205,206]

Basophils

Basophils and mast cells share functional similarities and are involved in immediate hypersensitivity reactions, as well as in longterm inflammatory or immunologic responses. Basophils secrete cytokines such as IL-4 and histamine, which can play a role in the ongoing allergic response.[207,208] Mast cells are released as precursors from the bone marrow and are found and mature in connective tissue, not circulating in blood. Basophils differentiate and mature in the bone marrow during a 7-day period, have a lifespan of only several days, circulate in blood, and are not normally found in connective tissue. Basophilia is said to occur when the peripheral blood basophil count exceeds 150/mm^3. Infection with parasites often is associated with increased levels of IgE, peripheral basophilia, or the infiltration of basophils and mast cells at sites of infection. Basophilia is highly associated with malignant myeloproliferative disorders and can be seen in patients with Hodgkin disease, hemolytic anemias, hypothyroidism, pregnancy, and nephrotic syndrome and with the use of estrogen and antithyroid medications. Infection, hyperthyroidism, adrenocorticosteroid administration, chemotherapy, and radiation therapy lower the basophil count. Mast cell disease and urticaria pigmentosa are associated with increased basophil counts in tissue and bone marrow, but not usually in peripheral blood.

Platelets

Physiology and Measurement

The process of megakaryopoiesis and platelet production is complex, with regulation at multiple steps.[209] Megakaryocytes derive from the hematopoietic stem cell through successive lineage commitment steps, with maturation and eventual shedding of platelets into the sinusoids within the bone marrow. Transcription factors and inflammatory cytokine and hematopoietic cytokine (thrombopoietin) signaling regulate the processes; acquired and inherited disorders can result in thrombocytopenia or thrombocytosis.[209] Platelets circulate for 7 to 10 days; approximately one third of these platelets are located in the spleen and two thirds in the circulation. The normal platelet count range is approximately 80,000 to 450,000 in the first week of life and 150,000 to 400,000/mm^3 thereafter. Spuriously high or low platelet counts can be reported when automated instruments are used.[210]

Mature platelets are disk-shaped cells 2 to 4 μm in diameter. In general, platelets tend to be larger in conditions with increased marrow production (acute phase response) or peripheral destruction (e.g., immune-mediated, mechanical breakdown, or consumption) and of normal size to small when production defects are present. The spleen is the site of destruction in the presence of platelet antibodies or as a result of sequestration. In hypersplenism, the weight of the spleen correlates directly with the degree of thrombocytopenia regardless of the cause. In thrombocytopenic states, large platelet size is not a completely reliable discriminator of increased destruction because some underproduction states (e.g., Wiskott-Aldrich syndrome) also are associated with qualitative abnormalities. Exercise or the administration of epinephrine causes immediate thrombocytosis as a result of the redistribution of mature platelets (lasting for minutes to hours), as does splenectomy (lasting indefinitely).

Thrombocytosis

Thrombocytosis is defined as >500,000 platelets/mm^3 and usually is a secondary or reactive event related to underlying conditions.[210,211] Primary causes of thrombocytosis (polycythemia vera and essential thrombocythemia, clonal myeloproliferative disorders) are unusual in childhood.[211] Causes of thrombocytosis and extreme thrombocytosis are listed in Table 288.3. Infection (25%–35% of cases) and rebound after infection (15% of cases) are most common, followed by hematologic causes (25%–35%). Production of GM-CSF secondary to any inflammatory response can induce thrombocytosis. The degree of thrombocytosis in bacterial infections is inversely related to age <5 years, the duration of the infection before treatment, and the presence of a tissue site of infection or abscess (e.g., complicated pneumonia, osteomyelitis, pyogenic arthritis, meningitis).[211–215] Thrombocytosis is the hallmark of the second week of Kawasaki disease. Extreme thrombocytosis in pertussis reflects severity of the disease.[168–170] Thrombocytosis is unusual in viral infections, except for necrotizing infection and HIV infection,[216] and during recovery from thrombocytopenia. Multiple drugs, including antibiotics, induce thrombocytosis. Thromboembolic events are rare with reactive thrombocytosis related to infection, and treatment should be aimed at the inciting infection rather than the platelet count.[215]

TABLE 288.3

Causes of Thrombocytosis in Children

Conditions	Thrombocytosis (500,000–1,000,000 Platelets/mm^3)	Extreme Thrombocytosis (>1,000,000 Platelets/mm^3)

+++, frequently seen in infection or condition; ++, not infrequently seen; +, occasionally seen or cases reported.

Thrombocytopenia

Thrombocytopenia is defined as <80,000 platelets/mm^3 in the first week of life and <150,000/mm^3 thereafter. Thrombocytopenia can have several mechanisms and causes[217] (Box 288.7). Infections commonly can downregulate platelet production as part of general hematopoiesis. Immune-mediated destruction during acute, chronic, or congenital infection can occur in several viral infections (e.g., CMV infection, EBV infection, HIV infection,[218] rubella, and hepatitis B and C[219]) and subacute bacterial infections (e.g., endocarditis, leptospirosis, and syphilis). Idiopathic thrombocytopenic purpura results from immune-mediated destruction, usually follows nonserious viral infections, and is characterized by profound thrombocytopenia and mucocutaneous bleeding in an otherwise healthy-appearing child.[220] Acute severe infections, viral or bacterial, can cause disseminated intravascular coagulopathy and profound thrombocytopenia on a nonimmunologic basis. Acute infections with *Rickettsia, Ehrlichia* and *Anaplasma,* and *Plasmodium* have a propensity to cause thrombocytopenia without overwhelming infection, and certain bacterial toxins (e.g., the endotoxins of enteric bacilli and the exotoxins of *S. aureus* and *S. pyogenes*) can cause thrombocytopenia without bacteremia. The Shiga-like toxin of certain *E. coli* organisms and the neuraminidase of *S. pneumoniae* are associated with microangiopathic thrombosis and thrombocytopenia in hemolytic uremic syndrome. The transient mild thrombocytopenia (platelet count of 80,000–150,000/mm^3) that occurs commonly during systemic viral illness is speculated to have marrow suppressive and peripheral destructive components.

Box 288.7

Causes of Thrombocytopenia in Children

Decreased Production

Aplastic anemia

Damaged, suppressed, or refractory marrow (infection, drugs, chemicals, radiation)

Replaced marrow (malignant disease, myelofibrosis)

Congenital, hereditary disorders

Ineffective thrombocytopoiesis (cobalamin, folate deficiency; dysplastic hematopoiesis)

Abnormal Distribution

Hypersplenism (congestive or infiltrative)

Immune-Mediated Destruction

Idiopathic thrombocytopenic purpura

Malignant diseases

Drugs (sulfa, ampicillin, rifampin, quinine, and multiple nonantimicrobial agents)

Infection (especially Epstein–Barr virus, cytomegalovirus, human immunodeficiency virus, hepatitis B and C, congenital syphilis, toxoplasmosis, viral infections, subacute endocarditis)

Vaccines

Autoimmune diseases

Nonimmune Destruction

Disseminated intravascular coagulation

Septicemia

Viral, rickettsial, fungal infection

Hemolytic uremic syndrome

Bacterial toxin–mediated syndromes

Malaria

Organ transplant rejection

Cyanotic congenital heart disease

Pseudothrombocytopenia

Aggregation of platelets not counted by electronic cell analyzers

Metabolic Abnormalities

Many infections result in some degree of associated hepatic dysfunction. Intrahepatic cholestasis secondary to hepatocellular dysfunction is the usual abnormality in systemic bacterial, toxin-mediated, viral, and rickettsial diseases. Serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) concentrations are elevated >1.5 times normal in >75% of people with ehrlichiosis, anaplasmosis,[160] and Rocky Mountain spotted fever[161] and in approximately one half of patients with staphylococcal toxic shock or streptococcal septicemia or toxin-mediated disease. AST exceeds ALT when hemolysis or rhabdomyolysis occurs. Serum hepatic enzymes are mildly elevated in EBV mononucleosis (almost universally) and CMV mononucleosis (frequently); characteristically, bilirubin (direct greater than the indirect fraction) is elevated disproportionately to the elevation of transaminases, with increases to ≥10 mg/dL in some EBV infections. In acute hepatocellular infections, as with hepatitis viruses, serum levels of the transaminases frequently exceed 1000 mg/dL, with only mildly elevated bilirubin. Neonates with disseminated herpes simplex virus, adenovirus, or enterovirus infections can have severe hepatocellular dysfunction. In a study of 85 episodes of bloodstream infection in neonates, 46% of cases caused by gram-negative bacilli but only 13% caused by coagulase-negative staphylococci were associated with elevated ALT and AST levels.[221] Some bacterial infections (e.g., tuberculosis, brucellosis, syphilis, cat-scratch disease) cause granulomatous space-occupying lesions in the liver that result in cholestasis, and bacterial cholecystitis can cause obstruction. Serum transaminases are mildly elevated in more than 50% of children with Kawasaki disease. Hypoglycemia secondary to impaired gluconeogenesis can result from a severe hepatic insult or septicemia. Hyperglycemia sometimes is a clue to candidemia in prematurely born infants.[222]

Hyponatremia is a complication of dehydration and diarrheal loss in childhood infections or a complication of vomiting in pyloric stenosis. Hyponatremia without apparent gastrointestinal fluid loss is a clue to increased vascular permeability and is associated in such situations with decreased albumin and intravascular volume. Hyponatremia is an early and almost universal finding (present in 90% of cases) in Rocky Mountain spotted fever, is present in >50% of patients with toxic shock syndromes, and is a common finding in nephrotic syndrome and cirrhosis. Edema despite decreased intravascular volume is a hallmark of these conditions. Hyponatremia in people with normal hydration and intravascular volume can be associated with inappropriate secretion of antidiuretic hormone as a result of central nervous system or pulmonary infection, or the disorder can be associated with infant botulism.[223] Serum potassium levels rise predictably with hemolysis or with thrombocytosis.[224]

Nonspecific Antibodies

Various nonspecific antibodies are produced in response to infectious, neoantigenic, and inflammatory stimuli. Beginning as serendipitous or enigmatic laboratory findings, some tests have become extremely useful in the diagnosis or management of infectious diseases, even though the antigen used does not contain any part of the infectious agent (Table 288.4). Measurement of nonspecific antibodies also can lead to confusion and misdiagnosis.

TABLE 288.4

Nonspecific Antibodies Associated With Infections and Other Conditions

Antibody	Infectious Agent or Condition	Antigen or Test	Antibody Class or Timing	Comments
Heterophile antibody	Epstein-Barr virus	Horse or sheep RBCs; agglutination (after guinea pig kidney adsorption step)	IgM Peak at 2–3 wk of illness; fall by 3 mo, negative by 6 mo	Positive in Epstein-Barr virus–associated mononucleosis in 90% of adolescents; <50% children <4 yr old False-positive result ≤10% (usually low titer) with multiple bacterial infections, viral (including human immunodeficiency virus) infections, and autoimmune disease
Cold agglutinin	*Mycoplasma pneumoniae*	Human type O RBCs (I antigen); agglutination at 4°C	IgM Peak at 2–3 wk of illness; positive for months	Titer >1 : 64 is >90% associated with *Mycoplasma pneumoniae* Titer correlates with severity of pneumonia Titers <1 : 64 found with respiratory tract viral infections, Epstein-Barr virus infection, cytomegalovirus infection, bacterial pneumonia, malaria, lymphoma, hypersensitivity syndromes
Reagin antibody	*Treponema pallidum*	Cardiolipin; multiple test methods (e.g., rapid plasma reagin, Venereal Disease Research Laboratory)	IgG/IgM Positive 1–2 wk after onset of chancre (slightly later than specific antibody); correlates with activity of infection or adequacy of therapy	False-positive result (i.e., negative specific treponemal antibodies) is rarely >1 : 4; found with *Mycoplasma pneumoniae* infection, malaria, bacterial and viral infections; after vaccination; in illicit drug use; and in autoimmune diseases
Rheumatoid factor	Autoimmune disorders	Fc fragment of human IgG; latex agglutination, enzyme	IgM Titer correlates with activity of infectious	Multiple autoimmune disorders (positive in only 25% with juvenile idiopathic arthritis); results

		immunoassays	disease, not necessarily autoimmune disease	can be positive in chronic infections (e.g., endocarditis, and hepatitis) and in neonates against maternal IgG
Antinuclear antibody	Autoimmune disorders	Nuclear and cytoplasmic antigens using Hep-2 cells; indirect immunofluorescence antibody test followed by specific antigen testing	IgG/IgM	Multiple autoimmune disorders; positive results in >90% with systemic lupus erythematosus Titer 1 : 20 in ≤10% of healthy children Titers 1 : 40 commonly and higher titers occasionally with bacterial, viral, toxin-mediated diseases (for ≤8 wk) Also associated with drug hypersensitivity, malignant disease

IgG, immunoglobulin G; IgM, immunoglobulin M; RBCs, red blood cells.

Anti-Infective Therapy

OUTLINE

289 Principles of Anti-Infective Therapy
290 Mechanisms and Detection of Antimicrobial Resistance
291 Pharmacokinetic-Pharmacodynamic Basis of Optimal Antibiotic Therapy
292 Antimicrobial Agents
293 Antifungal Agents
294 Topical Antimicrobial Agents
295 Antiviral Agents
296 Antiparasitic Agents

289

Principles of Anti-Infective Therapy

John S. Bradley, Sarah S. Long

The selection of optimal antibiotic therapy for presumed bacterial infection is based on the balance of benefits and risks of specific therapy for each child. Prescribing the right antibiotic or antibiotics early in the course of serious infection can save a life or avoid substantial morbidity. Inappropriate antibiotic therapy given to a child with a viral infection exposes the child needlessly to antibiotic toxicities, adds to the selective pressure driving antibiotic resistance in bacteria, creates unnecessary costs to the medical system, and can divert attention from evaluation and management of the child's condition.

Selecting Optimal Antimicrobial Therapy

Several questions must be addressed to choose optimal empiric and definitive antimicrobial therapy. These questions revolve around identifying potential or presumed pathogens and considering the relative merits of antimicrobial agents for specific pathogens and circumstances (Box 289.1). The clinician should follow the steps outlined in the following paragraphs.

Box 289.1

Questions Pertinent to Choosing

Antimicrobial Therapy Appropriately

1. What is the clinical syndrome or site of infection? Pathogens are predictable by site.
2. Does the child have normal defense mechanisms (in which case causative agents are predictable), or are these mechanisms impaired by underlying conditions, trauma, surgical procedures, or a medical device (in which case additional potential pathogens should be considered)?
3. What is the child's age? Pathogens are predictable by age.
4. What clinical specimens should be obtained to guide empiric definitive therapy?
5. Which antimicrobial agents have activity against the pathogens considered, and what is the current range of susceptibilities for each antibiotic against these pathogens in the practitioner's hospital or clinic?
6. What special pharmacokinetic and pharmacodynamic properties of a therapeutic agent are important regarding the site of the infection and the host?
7. For any given infection site, what percentage of children requires effective antimicrobial therapy with agents first selected for empiric treatment? Bacterial meningitis requires ~100%, whereas ~75% may be acceptable for impetigo.
8. In contrast to empiric therapy, what definitive therapy would be optimal? Agents with a broad spectrum of activity may be appropriate for empiric therapy, but those with a narrow spectrum of activity *are* preferred for definitive therapy.
9. What special considerations exist regarding drug allergy, drug interaction, route of administration, cost, alteration of flora, or selective pressure in an environment?

Step 1: Predict the Infecting Organism

Defining the patient's site or sites of infection or the organ system or systems involved can predict the pathogen or pathogens. Bacteria often are tropic for certain tissues; certain species have a proclivity for causing certain infections. Examples include the following: *Neisseria meningitidis*, group B *Streptococcus*, and *Streptococcus pneumoniae* for meningitis; *S. pneumoniae*, *Haemophilus influenzae*, and *Moraxella catarrhalis* for acute otitis media; and *Staphylococcus aureus* and *Streptococcus pyogenes* for cellulitis, osteomyelitis, and pyogenic arthritis.

Step 2: Consider Host Defense Mechanisms

Is the host healthy, with intact immunity and normal integumentary barriers to infection? If so, the causative pathogens often are predictable. If the child has an underlying condition such as a defect in granulocyte number or function, nonpathogenic bacteria from both the host and the environment can cause infection. For an immunocompetent child with trauma to skin or mucous membranes, a recent surgical procedure, or an indwelling medical device, a variety of relatively nonpathogenic commensals also can cause infection, thus mandating empiric therapy that provides activity against a much broader range of organisms.

Step 3: Consider the Age of the Child

Infectious agents causing specific target organ infections in immunocompetent hosts often are predictable based on the child's age and exposures to pathogens specific to each age group. For example, group B streptococci and *Escherichia coli* are causes of meningitis almost exclusively during the first 90 days of life. Developmental maturation of the immune system as children approach the third year of life provides improved recognition for polysaccharide-encapsulated pathogens such as *S. pneumoniae* or *H. influenzae* type b. Group childcare exposes young children to *Kingella kingae* and infection with antibiotic-resistant strains of *S. pneumoniae*. School-related exposure to *S. pyogenes* is associated with increased middle-school age-specific attack rates of streptococcal pharyngitis. Adolescents' exposure to sexually transmitted pathogens such as *Neisseria gonorrhoeae* increases the potential causes of pyogenic arthritis in that age group.

Step 4: Perform Diagnostic Tests

Every effort should be made to prove the origin of the infection and to obtain an isolate for susceptibility testing. The Gram stain is a useful, rapid test to provide clues to the pathogen (e.g., swab in neonatal conjunctivitis), pathogenesis (e.g., aspirate in polymicrobial lung abscess), or interpretation of culture results (e.g., tracheal secretions in pneumonia). Although a Gram stain result of a tissue sample can lead to the inclusion of additional empiric therapy, it should not necessarily lead to exclusion of antibiotics customarily used in the empiric treatment of that infection. An error in processing or interpreting the Gram stain must not lead to ineffective empiric therapy.

Nucleic acid detection is used increasingly for the diagnosis of bacterial, mycobacterial, viral, fungal, and parasitic infections. These techniques do not require isolation of viable organisms, and they can be applied to a variety of tissue specimens. Advantages of improved sensitivity are obvious, but causation cannot always be inferred, and current methods often lack the ability to provide data on antimicrobial susceptibility.

Step 5: Consider Antibiotic Susceptibilities of Suspected Pathogens

Bacteria can have multiple different mechanisms of resistance against a single antibiotic or against multiple types of antibiotics. The most common resistance mechanisms include cell wall permeability changes to prevent entry of the antibiotic into the pathogen, efflux pumps to eject antibiotics that enter the cell, bacterial enzymes that specifically inactivate antibiotics, and mutations that lead to alteration of the antibiotic's target binding site (see Chapter 290). Bacteria can express resistance continuously (constitutively) or only on exposure to an antibiotic (inducible resistance). With such vast biologic variability in resistance mechanisms, efficient transmission of resistance genes among organisms, and variations in antibiotic use that create selective pressure, it is understandable that a single species such as *E. coli* can manifest different patterns of antibiotic resistance in different populations within the same local region, among regions of a country, and among countries of the world. Each healthcare association or hospital has a widely available antibiogram tool that is updated annually and allows the clinician to assess the current local resistance rates of pathogens. The probability that the antibiotic selected for empiric therapy will be effective against the presumed pathogen is directly related to the proportion of susceptible pathogens infecting patients in that location.

Step 6: Consider Pharmacokinetic and Pharmacodynamic Properties of Drugs

The route of administration, the absorption, tissue distribution, and drug elimination characteristics are all critical pieces of information to guide the selection of both drug and drug dosage in antimicrobial therapy. Eradication of pathogens causing infection requires the appropriate antibiotic exposure at the infected tissue site. For many agents, published data describe the average concentrations and variability of concentrations achieved at specific tissue sites over time. Unfortunately, for many older antibiotics this important information often is unavailable.

To understand how likely an antibiotic will be in achieving a microbiologic cure, with otitis media and amoxicillin treatment used as an example, information is required on the range of amoxicillin concentrations achievable in the middle ear fluid (MEF) following administration of a specific mg/kg dose of amoxicillin. These data provide a measure of exposure of bacteria to amoxicillin in the middle ear fluid. Based on current knowledge, treatment success is linked to an amoxicillin exposure (in middle ear fluid in this case) that delivers an amoxicillin concentration higher than the minimal inhibitory concentration (MIC) of amoxicillin against the pathogen causing the infection, for at least 30% to 40% of each dosing interval. With this information, we can calculate the proportion of children given that specific dose who will likely respond to treatment. For different classes of antibiotics, different types of drug exposure may be required for bacterial eradication (see Chapter 291).[1]

In the treatment of meningitis, adequate antibiotic concentrations in the cerebrospinal fluid (CSF) are critical for cure. The concentration of aminoglycoside antibiotics in the CSF following intravenous infusion is likely to be inadequate to treat meningitis caused by gram-negative pathogens, even though CSF concentrations are approximately 20% of those achievable in serum. In contrast, the high serum concentration of penicillin after a large dose leads to a bactericidal CSF concentration against susceptible pneumococci, even though the CSF concentration of penicillin is only approximately 5% of that achievable in serum.

A range of predictable serum concentrations and tissue concentrations of antimicrobial agents exists within any group of children. This variability can be defined for all children receiving the same dose of drug, and it represents the basic concept of “population pharmacokinetics.” For example, antibiotic concentrations in the serum and middle ear space are usually therapeutic at a given mg/kg dose, but they can be inadequate in a small but predictable percentage of children. However, unlike with acute otitis media, the clinician cannot risk inadequate dosing for even 1 child with meningitis. Logically, a single mg/kg dose of an antibiotic may not be effective in all children even for the same pathogen that causes infection at different tissue sites because the tissue concentration of that antibiotic can differ substantially among sites (e.g., urine vs. lung vs. CSF).

The absorption, distribution, metabolism, and elimination of drugs are variable in children as a function of age-related developmental changes.[2,3] The volume of distribution of antibiotics varies profoundly during the first year of life, as the proportion of body weight contributed by extracellular water and fat changes. Drugs that distribute preferentially into the extracellular water (e.g., penicillins) require a dose and dosing interval that recognize greater diffusion into neonatal interstitial tissue than occurs in older infants and children. Drug elimination based on metabolism and organ function generally increases during the first several weeks of life, peaks in infancy, and approaches adult values during adolescence. Many antibiotics require different mg/kg dosages during a child's life to achieve optimal antibiotic exposure to maximize efficacy and minimize toxicity.

The pharmacodynamic properties of an antibiotic describe how exposure of the antibiotic to the pathogen leads to a bacteriostatic or bactericidal effect and are important in designing an antibiotic dosing regimen (Table 289.1). Aminoglycosides kill bacteria in a concentration-dependent fashion. Therefore, it is desirable to achieve the highest concentration possible at the site of infection to achieve the fastest killing of bacteria. The maximum safe tissue concentration is dictated by the serum aminoglycoside concentration above which renal toxicity occurs. For other antibiotic classes, such as the penicillins, achieving tissue concentration greater than the MIC for that pathogen for 30% to 40% of the dosing interval is associated with microbiologic and clinical cure. For the penicillins, a higher concentration of the antibiotic at the infected tissue site, higher than a certain critical concentration close to the MIC, is not associated with faster sterilization of tissues or a better clinical outcome.

TABLE 289.1

Pharmacodynamic Antibacterial Effect of Antimicrobial Agents by Primary Bacterial Target and by Antibiotic Class

Primary Target[a]	Antibacterial Class	Pharmacodynamics[b]	Intracellular Activity[c]
Cell wall	**β-Lactams (penicillins, cephalosporins, monobactams, carbapenems)** **Glycopeptides (vancomycin,[d] telavancin, dalbavancin, oritavancin, teicoplanin[e])**	Bactericidal Time-dependent inhibition Carbapenems PAE against gram-positive and gram-negative organisms PAE only against gram-positive organisms Bactericidal Concentration (AUC)–dependent inhibition	Generally not effective
Cell membrane	**Lipopeptides (daptomycin)** **Polymyxins (polymyxin B, colistin)**	Bactericidal Concentration-dependent inhibition Long PAE (daptomycin) PAE (polymyxins)	Not known
Ribosome	**Macrolides, azalides, ketolides**	Bacteriostatic primarily Time-dependent with long PAE Long PAE	Yes
	Tetracyclines, glycylcyclines	Bacteriostatic Time-dependent with long PAE	Yes
	Lincosamides (clindamycin)	Bactericidal or bacteriostatic Time-dependent with PAE	Yes
	Aminoglycosides	Bactericidal Concentration-dependent PAE	Generally not effective
	Oxazolidinones	Bacteriostatic (except against	Generally

		Streptococcus pneumoniae) Time-dependent with PAE	not effective
	Rifamycins	Bactericidal with long PAE	Yes
	Fluoroquinolones	Bactericidal Concentration-dependent with long PAE	Yes
	Streptogramins	Bactericidal (except against *Enterococcus faecium*) Time-dependent with PAE	Yes
Nucleic acid	**Metronidazole**	Bactericidal Concentration-dependent with PAE	Yes
	Sulfamethoxazole-trimethoprim	Bactericidal Concentration-dependent	Yes

[a] The primary antibiotic target within the bacterial pathogen.

[b] The type of pharmacodynamic relationship that best describes antibiotic-mediated inhibitory or bactericidal activity.

[c] The ability to treat intracellular pathogens, based on the penetration of antibiotic into the host cell by passive diffusion or by active uptake.

[d] Activity is best described by AUC concentration-dependent pharmacodynamics in animal models.

[e] Not marketed in the United States.

AUC, area under the curve; PAE, postantibiotic effect, or the observation of delay in regrowth of organisms following removal of antibiotic from the media.

The postantibiotic effect also is considered in dosing and varies by antibiotic (see Table 289.1). For the aminoglycosides, the postantibiotic effect is profound (i.e., an extended period of time lapses after the antibiotic concentration drops to less than the MIC before regrowth occurs). Conversely, other antibiotics (e.g., most penicillins) inhibit growth only until the concentration drops to less than the MIC. Differences probably reflect molecular mechanisms of antibiotic activity at the target site, the avidity of antibiotic binding to the target site, the rate of elimination of the antibiotic from the target site, and whether the damage to the target site structure is reversible or irreversible.

Although growth of a population of organisms generally can be inhibited at a certain antibiotic concentration (the MIC) as defined by standard laboratory techniques, antibiotic concentrations that lead to less frequent emergence of resistance often can be determined by using unique assay conditions with higher inocula than those used in standard clinical assays. For some bacteria, resistance begins with a spontaneous nucleic acid mutation leading to an amino acid change that results in less avid binding of the antibiotic to the target site (well described for fluoroquinolones and *S. pneumoniae*). This single-step mutation may lead only to a slightly higher MIC. The antibiotic concentration required to inhibit the single-step mutant, however, may not be achievable in infected tissues when a standard antibiotic dosage is used. Second-step mutations may then occur during ongoing exposure to an antibiotic, thereby leading to more profound changes in the MIC and rendering the organisms fully resistant even at the highest attainable tissue concentrations. Often it is possible to identify the concentration of antibiotic required to prevent the selection of viable single-step mutants, the mutant prevention concentration (MPC); the MPC often is two- or threefold higher than the MIC.[4,5] If the higher dosage required for the MPC can be prescribed without undue toxicity, the risk of selecting antibiotic-resistant strains that can subsequently infect that child or his or her contacts may be reduced.

Step 7: Consider Target Attainment

In treating any child, the practitioner must assess the seriousness of the infection and the risk of injury or death if the antibiotic is not effective. For infections that are not life-threatening and cause minimal morbidity (e.g., impetigo), achieving a cure rate of 70% to 80% with a safe and inexpensive antibiotic often is acceptable, especially if the use of an alternative agent to achieve a 98% success rate for that infection carries an excessive risk of toxicity or high cost. For other infections that cause a higher degree of suffering or risk of organ damage (e.g., pyelonephritis or acute otitis media), a cure rate of 80% to 90% often is desirable. For serious, life-threatening infections (e.g., bacterial meningitis or septicemia in a neutropenic child), an expected bacteriologic cure rate of close to 100% must be achieved.[1] No formal list of “approved” cure rates or “target attainment” rates exists. Accepted target attainment rates can differ among infections and hosts as assessed by physicians, families, and societies. Consideration of target attainment rates can help clarify decision making regarding relative merits, risks, and costs of antimicrobial management.

Step 8: Consider Empiric and Definitive

Therapeutic Decisions Separately

For suspected serious infections, antibiotics with appropriately broad antibacterial activity at the highest tolerated dosage are selected for empiric therapy. Adequate empiric therapy is associated with decreased mortality rates and shorter hospital stays compared with inadequate empiric therapy for seriously ill adults.[6–9] For the seriously ill child, knowledge of local resistance patterns for suspected pathogens should lead to selection of antibiotics with a likely achievable bacteriologic cure rate of >95%.

Combination empiric therapy frequently is given when high cure rates are desirable to ensure adequate antimicrobial activity against all potential pathogens. A combination of vancomycin and a third-generation cephalosporin is used for empiric treatment of community-acquired meningitis because the use of a third-generation cephalosporin alone may not provide optimal therapy for *S. pneumoniae* with resistance to β-lactam agents. Empiric therapy for meningitis in the first 2 months of life consists of ampicillin in combination with a third-generation cephalosporin because the possible pathogens include *Listeria monocytogenes,* group B *Streptococcus,* and *E. coli.* Long-established combination therapies can be used for febrile neutropenic patients to ensure activity against *Pseudomonas aeruginosa,* enteric gram-negative bacilli, and *S. aureus.*[7] Once the pathogen is identified, a narrow-spectrum agent frequently can provide the same degree (or a higher degree) of bacterial eradication and clinical efficacy with decreased toxicity, decreased selective pressure, and decreased cost. For example, initial therapy with a carbapenem agent for a patient with ventilator-associated pneumonia can be narrowed to cefotaxime if the pathogen isolated is a susceptible *Klebsiella* species rather than *P. aeruginosa.* In a patient with a postoperative wound infection, treatment with vancomycin and cefotaxime can be narrowed to ampicillin if a susceptible *E. coli,* rather than methicillin-resistant *S.* (MRSA) or *Klebsiella* species, is isolated. For a patient with catheter-associated septicemia who is treated with vancomycin and gentamicin and from whom ampicillin-susceptible *Enterococcus* is isolated, ampicillin has superior antibacterial activity (and less toxicity) than vancomycin. For an outpatient with a cutaneous abscess presumed to be caused by *S. aureus,* empiric clindamycin can be replaced with an oral first-generation cephalosporin or β-lactamase-stable penicillin if the organism is methicillin susceptible.

Definitive, convalescent outpatient therapy of serious infections initially treated in the hospital is reasonable if the risks of complications of the infection are negligible and if the parents and child can adhere to well-defined management plans and can return to the hospital quickly for any infection- or therapy-related problem. In some situations, either convalescent oral therapy or convalescent parenteral therapy is preferred. High-dose oral β-lactam therapy for bone and joint infections is one of the best evaluated step-down therapies for invasive infection.[10] Parenteral antibiotics, such as ceftriaxone, that can be administered once daily are advantageous for outpatient therapy even though agents with a narrower spectrum of activity (or more potent activity) may be available because the narrower-spectrum or more potent agents require more frequent doses that may not be realistically administered in a home environment.[11]

Step 9: Special Considerations

Considerations of drug allergy affect antimicrobial selection. The degree and type of drug reaction should be ascertained. The history of a morbilliform rash in a child 4 days after commencing amoxicillin therapy does not carry the same risk of a serious drug reaction as does the history of hives and airway obstruction following the first dose of amoxicillin. Cost considerations have become a greater issue as health insurers and governmental agencies develop antibiotic formularies that contain “approved,” less costly antibiotics with a narrow spectrum of activity. Antibiotic resistance of the suspected pathogen provides guidance for the selection of a particular agent. As antibiotic resistance in a community increases and failures with older, less active agents increase, formularies must be reassessed. An acceptable risk of failure must be determined by the treating physicians as well as by medical advisors to government and private insurers who determine formularies, to allow families to achieve acceptable cure rates and continue to have confidence in their healthcare providers.

Antimicrobial Susceptibility Testing and Interpretation

The primary purposes of performing antimicrobial susceptibility testing on clinical isolates are to guide therapeutic decisions for individual children and to amass data on susceptibilities of pathogens to a wide range of antibiotics to inform future decisions when a pathogen is not isolated. Susceptibility testing is performed routinely for most clinical isolates to inform decisions for individual children, with a few notable exceptions, such as for *S. pyogenes,* for which susceptibility to penicillin (but not macrolides) is predictable. A comparison of the antibiograms from sequentially isolated organisms from a child can provide guidance for interpretation of the clinical relevance of 2 or more isolates (e.g., coagulase-negative staphylococci as a true pathogen vs. contaminant). Comparing antibiogram data from the same bacteria isolated from several children on a hospital unit can provide insight into possible healthcare-associated infections.

Interpretation of Susceptibility Test Results

An assortment of routine susceptibility test methods can be performed, including the disk diffusion (Bauer-Kirby) test, an antibiotic strip gradient-diffusion method (E-test), agar dilution with a mechanized inoculator, broth macrodilution or microdilution, and a short-incubation automated instrument method[12] (see Chapter 286). Results usually are provided as a measure of the inhibition of growth of a defined inoculum of organisms following incubation in the presence of defined concentrations of an antibiotic. The MIC value provides an operational definition of a strain's intrinsic antibiotic susceptibility and generally reflects the additive effects of multiple mechanisms of resistance, if present. Standardizing these susceptibility techniques and interpretation largely has been the task of the Food and Drug Administration (FDA) with the assistance of the Clinical and Laboratory Standards Institute (CLSI) and the United States Committee on Antimicrobial Susceptibility Testing (USCAST), both nonprofit organizations composed of participants from the pharmaceutical industry, the FDA, and academic institutions.

Interpretation of the clinical relevance and direct clinical applications of MIC values are required beyond simple reporting of an MIC value.[13] The misunderstanding that absolute values of the MICs can be compared across antibiotics can lead to errors in antibiotic management. Examples of misinterpretation could be that ampicillin and gentamicin MICs of 4 μg/mL for *E. coli* denote equivalence, or that the vancomycin MIC of 1 μg/mL and the ampicillin MIC of 2 μg/mL for *Enterococcus* denote the superiority of vancomycin. The variables inherent in disk susceptibility testing were discussed in the landmark report by Ericsson and Sherris,[14] which formed the basis for the categorical interpretations recommended by Bauer and colleagues[15] and subsequently the FDA and professional organizations that interpret in vitro susceptibility test results.[16]

The interpretation of the susceptibility test results is provided by the laboratory report as "S" (susceptible), "I" (intermediate), or "R" (resistant). A report result of "S" suggests that treatment with standard FDA-approved dosages can be expected. A report result of "I" suggests that some clinical failures can be expected at standard dosages because of decreased susceptibility of the pathogen to that antibiotic. A report result of "R" suggests that a microbiologic cure is unlikely because the pathogen is not inhibited by the antibiotic at achievable tissue concentrations following administration of standard, FDA-approved doses, infusion times, and infusion intervals. Interpretation is most valid when the distribution of MIC values across several hundred clinical isolates indicates a widely spaced, distinctly bimodal distribution of susceptible and resistant strains, such as *S. aureus* for penicillin and *E. coli* for ampicillin. The MIC value at which an organism changes from susceptible to nonsusceptible is called the breakpoint.[13] The uniformity of reporting a single interpretation (S, I, or R) of a breakpoint for all infections caused by a single pathogen frequently is too simplistic and can be misleading, such as demonstrated by selecting a breakpoint when assessing the continuum of MIC values of penicillin for *S. pneumoniae* or MIC values of aminoglycosides for *P. aeruginosa.* The interpretation by clinicians of the clinical significance of MICs should be based on (1) the susceptibility values in a large population of isolates (range and mode of distribution, e.g., unimodal, bimodal, skewed), (2) the clinical pharmacology and pharmacodynamics of the drug (protein binding, volume of distribution, tissue concentrations over the dosing interval), and (3) clinical and microbiologic efficacy derived from prospective animal models and human clinical investigations.

At the time an antibiotic is first approved for use by the FDA, MIC interpretative breakpoints are assigned to the antibiotic for various pathogens (often for specific tissue sites). As organisms develop new mechanisms for resistance following widespread use, the interpretation of the susceptibility results (the breakpoints) for a particular organism and a particular antibiotic can change. When ceftriaxone was first approved for use in children, *S. pneumoniae* was considered susceptible if the MIC value was ≤8 μg/mL. Pneumococci then expressed a novel mechanism of resistance, alteration in the many different penicillin-binding sites on the various cell wall synthesizing transpeptidase enzymes. Beginning in 1990, microbiologic failures in the treatment of meningitis occurred in children infected by organisms with a ceftriaxone MIC of 2 μg/mL. The breakpoints subsequently were changed so that only organisms with MIC ≤0.5 μg/mL were considered susceptible. However, with the knowledge that ceftriaxone concentrations in tissues such as lung or soft tissue are higher than in CSF, prospective data were collected that documented clinical and microbiologic success of ceftriaxone for infections outside the central nervous system in which the MIC for *S. pneumoniae* was up to 2 μg/mL. Therefore, 2 breakpoints for ceftriaxone now are used: a lower breakpoint of ≤0.5 μg/mL, considered "S" for central nervous system infections, and a higher breakpoint of ≤1 μg/mL, considered "S" for infections outside the central nervous system (see Table 123.2).

To add to the confusion regarding multiple breakpoints assigned to a particular antimicrobial agent and pathogen pair while recognizing that intravenously administered penicillin achieves far higher concentrations in serum and tissues than does orally administered drug, 2 new breakpoints for penicillin for *S. pneumoniae* also have been accepted: a lower breakpoint of ≤0.06 μg/mL, considered "S" for oral drug administration; and a higher breakpoint of ≤2 μg/mL, considered "S" for intravenous drug administration.[17]

The process of regular review of breakpoints for important pathogens against commonly used older, generic antibiotics has been legislated and will become standard in the near future. When the MIC value leads to an "S" interpretation in the laboratory report, the clinician should not assume that an antibiotic will always be effective for all infections at all tissue sites. Furthermore, because "S" indicates bacterial *inhibition* in the test system, the clinician must know whether the antibiotic is bactericidal, which can be required for certain infections (meningitis) or for certain hosts (those with neutropenia).

Site of Infection

As a rule, only free, non–protein-bound drug is active in eradicating bacteria. For β-lactam agents, successively higher concentrations of antibiotic above the MIC present at the site of infection are not more efficacious in bacterial eradication because this class of agents displays time-dependent killing. Conversely, higher concentrations at the site of infection may enhance killing for aminoglycosides and other concentration-dependent drugs. Additionally, subinhibitory concentrations are not always ineffective; morphology and microbial adherence properties can be altered after exposure to subinhibitory concentrations of some antibiotics, with phagocytosis and intracellular killing subsequently enhanced by neutrophils.

Extracellular Infections

Many bacterial infections occur in interstitial tissue fluid.[18] For such infections, serum concentrations of antibiotics generally predict responses adequately. Antibiotics leave the vascular compartment and enter the extracellular fluid through passive diffusion. When the ratio of the surface area of vascular tissue to the site or volume of infection is high (e.g., in cellulitis, pneumonia, or pyelonephritis), antibiotic concentrations at that site are predicted by principles of passive diffusion. This is not the case when the volume of infection exceeds the surface area of the vasculature (e.g., abscess, fibrin clot, or cardiac vegetation). Passive diffusion principles alone also cannot be used to predict the extracellular fluid concentration of certain antibiotics at sites with active transport (e.g., urine or bile) or with a barrier to capillary permeability (e.g., into the ocular aqueous humor and CSF). The ability of antibiotics to pass through membranes by nonionic diffusion is related to lipid solubility. Lipid-soluble agents such as rifampin, chloramphenicol, trimethoprim, and isoniazid penetrate membranes and cross the blood-brain barrier better than the more highly ionized aminoglycosides. For meningitis, relatively large dosages of third-generation cephalosporins, penicillin G, ampicillin, or vancomycin are required to achieve adequate concentrations in the CSF. Additionally, active transport out of the extracellular fluid, including the CSF, also can result in reduced concentrations in CSF of certain antibiotics such as β-lactam agents.

Table 289.1 delineates the distribution characteristics of the major classes of antibiotics. Clinical evidence has indicated the inferiority of certain antibiotics used for the treatment of infection at sequestered tissue sites where penetration is poor (e.g., brain, eye, bone), and logical preference exists for the use of antibiotics known to accumulate at the site of infection. The vegetations of endocarditis, devitalized tissue, and bones are areas in which the penetration of most agents can be poor; high-dose and prolonged parenteral therapy usually is required, and surgical debridement of necrotic, nonperfused tissue can be necessary. The pharmacology of the drug can offer particular advantages. Agents eliminated by glomerular filtration or renal tubular secretion accumulate in urine. Fluoroquinolones, a few β-lactam agents (e.g., ceftriaxone and cefoperazone), and doxycycline are actively transported into bile, whereas first-generation cephalosporins and aminoglycosides diffuse passively. Clindamycin and the fluoroquinolones achieve excellent concentration in bone, although for infected bone with vascular necrosis, penetration of any antibiotic can be compromised.

Only free drug is considered capable of antibiotic activity.[19] Although only free drug passes through capillary walls and fibrin clots, intercompartmental diffusion will ultimately achieve an equilibrium between bound and free drug in tissues. Complex interactions at the tissue site probably account for the inconsistencies in prediction of clinical efficacy solely as a result of the degree of protein binding. In general, the plasma protein binding of aminoglycosides and fluoroquinolones is low, whereas binding for β-lactams can vary from low to very high for β-lactam agents.

Multiple factors at the site of infection also can alter antimicrobial activity. Examples include the presence of purulent material, which results in a tissue environment with low pH. This situation leads to a decrease in the cationic aminoglycoside molecule charge that results in decreased binding and decreased antibacterial activity at the site of infection. Pathogens such as *Bacteroides* and *Prevotella* produce β-lactamase and can hydrolyze β-lactam agents.[20] A wound hematoma can lower the ratio of the surface area of vascular tissue to the site or volume of infection; hemoglobin can bind penicillins and tetracyclines.[21] Low oxygen tension in abscesses or ischemic tissue impairs active transport of aminoglycosides into bacterial cells. Although an acid pH in tissue or urine impairs the activity of aminoglycosides, nitrofurantoin, and methenamine, an alkaline pH enhances the activity of aminoglycosides and clindamycin. A high–bacterial-density infection such as streptococcal necrotizing fasciitis can be associated with slowed growth of bacteria with downregulation of cell wall transpeptidases that are the targets for β-lactam agents, thus making the organisms temporarily less susceptible to β-lactam antibacterial activity.[22] The presence of a foreign body protects some organisms from host bactericidal action through biofilms and inhibition of neutrophil phagocytosis and, in addition, probably protects the pathogens by other, less well-defined mechanisms.

Intracellular Infections

The unique properties of antimicrobial agents must be considered when the site of infection is intracellular because many antibiotics do not penetrate human cells (see Table 289.1). β-Lactam antibiotics, for example, are confined almost exclusively to plasma water and the interstitial fluid space. Such localization explains some discrepancies between apparent in vitro activity and therapeutic ineffectiveness. Intracellular pathogens include *Listeria monocytogenes, Salmonella, Brucella, Legionella, Mycobacterium, Rickettsia,* and *Toxoplasma,* as well as some pathogens that can cause persisting infections such as *S. aureus* and *E. coli.* Antibiotics that enter cells do so by a variety of mechanisms, including diffusion of relatively small lipid-soluble agents across a concentration gradient, pinocytosis of water-soluble agents, and carrier-mediated transport.[23,24] Cellular accumulation of drug does not necessarily translate into efficacy against intracellular organisms; efficacy depends on whether the microbe and the drug are at the same intracellular site, how avidly the drug is bound to intracellular proteins and to the pathogen target site, and the molecular charge of the antibiotic at its intracellular location.

Clindamycin, macrolides, and azalides are tropic for lysosomes, where they become protonated and concentrated.[24,25] Fluoroquinolones have a large volume of distribution and a high tissue-to-serum ratio, as well as low-affinity intracellular binding; much of the fluoroquinolone body load thus is present intracellularly. For azithromycin, an even more dramatic intracellular location of antibiotic has been documented within phagocytic cells.[24,25] The pharmacokinetic properties and intracellular accumulation of azithromycin are responsible for successful therapy of infection with intracellular pathogens and for shortened courses with respect to the number of days of antibiotic dosing required (including single-dose therapy).[26] At the same time, azithromycin concentrations in serum, CSF, and the aqueous humor of the eye are negligible.[27]

Dosing, Route, and Duration of Therapy

Optimal dosing of an antimicrobial agent depends on relationships among the time course of concentration at the site of infection, the characteristics of antimicrobial activity, and adverse effects.

In clinical practice, the route of administration of antibiotics often is based on additional practical considerations. Parenteral administration is required if an agent is absorbed poorly from the gastrointestinal tract, if a condition precludes administration or absorption of a usually well-absorbed drug, if an unusually high tissue concentration of drug is required, or if adherence to an oral regimen for treatment of a significant infection cannot be ensured. Otherwise, substitution of oral for parental agents frequently is possible, even for serious diseases (e.g., pneumonia, osteomyelitis, pyogenic arthritis, orbital cellulitis) during convalescence.

Oral therapy can replace parenteral therapy when highly absorbed and bioavailable agents are used to treat highly susceptible pathogens (e.g., trimethoprim-sulfamethoxazole for *Pneumocystis* pneumonia) and when the tissue concentrations of drugs at relevant sites are uniquely favorable (e.g., clindamycin or fluoroquinolone in bone). With a less favorable profile, parenteral therapy is given for the entire duration of therapy (at home or in the hospital). Abundant evidence for the effectiveness for different routes of administration is available when patient screening, selection of medical conditions, and follow-up are performed diligently.[10,11,28] Advocacy for the best route of treatment of a child's infection is a paramount consideration, with the risk of failure of therapy and the impact of the outcome taken into account.

The appropriate duration of antibiotic therapy has been described more by experience and by “standard” treatment courses used for FDA antimicrobial drug approval than by prospective, well-controlled studies with duration of therapy as a separate variable as a specifically assessed outcome. Many factors are considered in the decision regarding the duration of therapy, including the intrinsic pathogenicity of the microbe, susceptibility to the agent used, the site of infection and penetration of the antibiotic, the use of synergistic combination therapy, the replication rate of the pathogen, the presence of a foreign body, and host factors that impair bactericidal capacity. In many situations, the severity of infection in all children is not uniform (e.g., pyelonephritis, soft tissue abscess), thus leading to differences in the time course of the child's response to antibiotic therapy. In children with more severe pneumonia, treatment can be given parenterally until a clinical (and presumed microbiologic) response has occurred, and then oral convalescent “step-down” therapy can be provided for a defined time to achieve the desired total duration of therapy. With all infections, a recommendation for duration of therapy is based on the best available information for that child's infection. Longer treatment courses can be more appropriate for more resistant organisms, for more severe infections associated with abscess formation especially if abscesses cannot be drained adequately, or for immunocompromised hosts. Delayed eradication of pathogens from the site of infection can occur in all these situations. The family should always be cautioned at the end of the treatment course to be alert for the signs and symptoms of relapse.

Antimicrobial Combinations

Prevention of Emergence of Resistance

Antibiotics can be used in combination in an attempt to (1) prevent or delay the emergence of drug-resistant subpopulations of the pathogen, (2) create synergy to improve outcomes, or (3) provide empiric therapy that will ensure that at least 1 antibiotic in the combination will be active against the infecting pathogen or pathogens. In most circumstances, published clinical data have been analyzed retrospectively with various antibiotic combinations for multiple infection entities, with conflicting conclusions.[29–31] For certain populations of children, particularly those critically ill and with immunocompromise, combination therapy will likely improve outcomes, as suggested by retrospective subset analyses.[30,31] Current data document improved outcomes with early, appropriate combination antibiotic therapy in sepsis.

Mycobacterium tuberculosis treatment provides the best clinically documented example of the prevention of emergence of resistant bacteria. With a spontaneous resistance mutation frequency of approximately 10^8, the initial use of 2 or more agents to which the organism is reported as susceptible substantially reduces the probability that resistant organisms will be selected out and emerge during therapy.[32] Treatment of *Pseudomonas* infection with a β-lactam, a fluoroquinolone, or an aminoglycoside alone can be associated with the emergence of resistant strains; 2-drug combination therapies can reduce the incidence of resistance to either component antibiotic. However, each antibiotic must provide the necessary exposure to pathogens in the infected tissues to ensure eradication of susceptible organisms. Inadequate dosing or poor tissue penetration of 1 antibiotic in a combination can lead to the selection of organisms resistant to that agent, despite the use of dual therapy.

Rifampin is an antibiotic that is never used alone for the treatment of infection because of the rapid, frequent development of resistance following antibiotic exposure. Combining rifampin with vancomycin for coagulase-negative staphylococcal prosthetic valve endocarditis or ventriculoperitoneal shunt infection, or with a semisynthetic penicillin for *S. aureus* infections, can reduce the emergence of resistance while taking advantage of the unique tissue penetration and target site activity of rifampin.

Inhibition of β-Lactamases

With certain fixed-combination drugs containing a primary β-lactam agent, the site of action of the second drug in the combination is not a vital microbial target binding site but rather the pathogen's antibiotic-degrading enzyme, responsible for resistance to the primary antimicrobial agent. Antistaphylococcal penicillins such as methicillin and nafcillin are degraded by staphylococcal β-lactamases. β-Lactamase inhibiting agents such as clavulanic acid, sulbactam, tazobactam, and avibactam display a specific affinity for and a degree of irreversible binding to the various bacterial β-lactamase enzymes, thereby protecting the companion β-lactam antibiotic from hydrolysis and allowing access to the target penicillin-binding proteins.[33] Amoxicillin-clavulanate is especially useful in children when the potential causative pathogens are susceptible to amoxicillin except for the presence of β-lactamases produced by the pathogen (*M. catarrhalis, H. influenzae, S. aureus,* and *Bacteroides fragilis*). Piperacillin-tazobactam is a useful agent that extends the spectrum of activity of piperacillin to include additional gram-negative bacilli and methicillin-susceptible staphylococci; it may not, however, add to the activity of piperacillin alone against *Pseudomonas* because tazobactam does not effectively inhibit many of the β-lactamases produced by *P. aeruginosa.*

Synergy

Target Site Synergy

Combinations of antimicrobial agents can have a variety of effects on the target sites of an organism in vitro. The combination can be categorized as follows: (1) *synergistic,* when the combined effect of the drugs is significantly greater than the independent effects when the drugs are tested separately; (2) *antagonistic,* when the combined effect is significantly less than the drugs' independent effects when tested separately; (3) *additive,* when the combined effect is the sum of the separate effects of the drugs tested; or (4) *indifferent,* when the combined effect is simply the effect of the more active drug alone. The clinical applications of these definitions are controversial. Synergy test results depend on the intrinsic activities of each antibiotic on an organism, the test system used, and whether the binding sites are similar or dissimilar.[34–37] Despite the paucity of prospective clinical validation of in vitro results, biologically plausible reasons exist to believe that for certain infections, synergy has clinical relevance. Although performing prospective clinical studies for all combinations is not practical, concepts on classes of drugs with differing intracellular sites of activity and encouraging supportive in vitro data have evolved (e.g., penicillins in combination with aminoglycosides) to guide therapeutic choices. In clinical practice, combination therapy is common for serious infections, as demonstrated in a retrospective study of severe MRSA infections in which 50% of children received 3 or 4 agents simultaneously.[38] With the combination of multiple agents, antagonism also can occur, and outcomes can be worse than with the use of only 1 or 2 agents.

Simultaneous Inhibition of Multiple Interrelated Targets

A classic example of synergy of targeted activity at consecutive metabolic steps is represented by the combination of a sulfonamide with a dihydrofolate reductase inhibitor such as trimethoprim. The resulting inhibition of consecutive steps in the folic acid pathway leads to a significantly reduced MIC and can also enhance the drug's bactericidal capacity. Streptogramin antibiotics (quinupristin-dalfopristin) include 2 biochemically distinct bacteriostatic compounds produced by *Streptomyces* that produce bactericidal activity when the agents are used in combination.[39] The binding of the type A streptogramin at the acyl-amino transfer RNA (tRNA) acceptor site on the ribosome both prevents the binding of tRNA and also causes a conformational change in the ribosome, which enhances the binding of the type B streptogramin and thus causes steric hindrance to the extrusion of newly formed polypeptide chains from within the ribosome.

Combination of Cell Wall–Active Agents With Ribosomal-Active Agents

Some instances of antibiotic resistance (e.g., to aminoglycosides) can result from a permeability barrier that precludes the drug's reaching the intracellular target site. Agents that act on the cell wall (e.g., β-lactam agents, vancomycin) should enhance intracellular entry of an aminoglycoside. Unless the drug is rendered ineffective by aminoglycoside-modifying enzymes or resistance occurs at the ribosomal level, a combination could be expected to be synergistic. Such bactericidal synergy is demonstrable for viridans streptococci, group B streptococci, enterococci, staphylococci, *Listeria* and *Corynebacterium* species, *P. aeruginosa,* and Enterobacteriaceae. Generally for *Enterococcus,* streptomycin, gentamicin, and tobramycin are predictably synergistic with cell wall–active agents if the enterococcal strain is susceptible to aminoglycosides at 2000 μg/mL; laboratories provide standardized testing at this single-drug concentration.

For gram-negative bacilli, exposure to aminoglycosides can enhance the permeability of the outer cell envelope to β-lactam antibiotics because of aminoglycoside-mediated production of altered, nonfunctional proteins that are incorporated into the cell wall.

The superior clinical efficacy of combination over single-drug therapy has been documented in only limited clinical settings. For the treatment of enterococcal endocarditis, penicillin alone, which provides only bacteriostatic activity against enterococci, results in an unacceptable relapse rate. The addition of an aminoglycoside such as streptomycin or gentamicin results in clinical cure rates comparable with the rates attained in the treatment of endocarditis caused by penicillin-susceptible streptococci.[40] Although similar clinical benefit is demonstrable in the animal model of endocarditis caused by penicillin-tolerant or relatively penicillin-resistant viridans streptococci (MIC of 1 μg/mL), no advantage is shown against fully susceptible strains; nonetheless, combination therapy for 2 weeks in patients with susceptible strains results in success rates comparable with those achieved when penicillin is administered alone for 4 weeks.[40] The combination of nafcillin and gentamicin is synergistic in vitro against methicillin-susceptible strains of *S. aureus;* both retrospective data and limited prospective, comparative trials of nafcillin and gentamicin versus nafcillin alone in adults with endocarditis, as reviewed by meta-analysis, failed to show any longterm outcome benefit of combination therapy.[41] Similarly, tolerance to the bactericidal effect of β-lactam agents among streptococci and staphylococci can be overcome in vitro by drug combinations, but superior clinical efficacy in human infections has not been proven. Combinations of ticarcillin or piperacillin with gentamicin, tobramycin, or amikacin exhibit in vitro synergy against many strains of *P. aeruginosa*. One prospective, randomized clinical trial of bacteremic patients with cancer confirmed better survival with carbenicillin in combination with gentamicin versus carbenicillin alone.[42] Another prospective, but uncontrolled study of 200 patients with *Pseudomonas* bacteremia documented increased survival in patients receiving combinations, regardless of whether synergy was demonstrable in vitro.[43] Confirmatory clinical evidence of the superiority of combination therapy for bacteremia caused by other gram-negative bacilli has been limited to neutropenic patients; such evidence documents the critical importance of susceptibility to the β-lactam component.[42,44,45] With the advent of more potent, highly bactericidal agents such as the third-generation cephalosporins and carbapenems, the benefit of addition of an aminoglycoside can be difficult to demonstrate except under the most challenging clinical conditions of sequestered pathogens and an absent host response at the site of infection. Prospective, controlled studies under these conditions are not likely to be performed. A retrospective analysis of more than 4500 bacteremic adults in intensive care units who were treated early with combination therapy documented decreased mortality rates and shorter hospital stays compared with patients who were given monotherapy, for both gram-negative and gram-positive pathogens.[31,46]

Published data exist on the effect of in vitro combination testing for antimicrobial agents approved during the past few decades against common pathogens. Data on some older drugs also may exist, particularly for currently isolated pathogens that can be multidrug resistant. For example, clindamycin and gentamicin in vitro have been reported to show synergy against some strains of viridans streptococci and antagonism against other strains.[47] Some studies have shown synergy of trimethoprim-sulfamethoxazole in combination with amikacin against Enterobacteriaceae for organisms that are susceptible to both drugs.[48] Ciprofloxacin in combination with an aminoglycoside or various β-lactam agents is infrequently synergistic against Enterobacteriaceae, but it can be synergistic against strains of *P. aeruginosa* with aminoglycosides or carbapenems[49]; antagonism is rare. When daptomycin was tested in combination with rifampin or gentamicin against MRSA, additive or indifferent effects usually were observed, without synergy or antagonism. Daptomycin in combination with β-lactam agents showed unexpected synergy in vitro against MRSA. The clinical relevance of these findings requires human clinical investigation.[50] Rifampin has synergistic bactericidal activity with vancomycin against coagulase-negative staphylococci[51] and with ampicillin against *Listeria*.[52] The unique tissue penetration properties of rifampin make it useful not only in postexposure prophylaxis to prevent or eliminate microbial colonization with meningococcus, but also in combination therapy for infections related to medical devices.

Antagonism

Despite the paucity of documented reports of the clinical significance of antagonism among antimicrobial agents, multiple examples are demonstrable in vitro; thus caution is needed in their use, especially for infections in hosts with impaired defenses. Combinations of a bacteriostatic agent with a β-lactam antibiotic can antagonize the bactericidal activity of the β-lactam antibiotic, as documented with the combination of chloramphenicol and ampicillin against group B *Streptococcus*. Combinations of chloramphenicol or tetracycline and aminoglycosides also are also antagonistic for gram-negative bacilli. In addition, chloramphenicol antagonizes the bactericidal effect of ciprofloxacin against *S. aureus, E. coli,* and *P. aeruginosa*. In a combination of agents that bind to similar locations within the ribosome (e.g., clindamycin, erythromycin, spiramycin, chloramphenicol, streptogramins), the drugs can either complement each other and enhance activity or compete with each other and antagonize activity.[53]

Judicious Use of Antibiotics (Antimicrobial Stewardship)

Antimicrobial agents are the principal therapeutic tools for pediatric infectious disease specialists and are among the leading interventions in all of pediatrics. Overuse of this tool is increasingly threatening its effectiveness. In 2009, $10.7 billion was spent on antibiotic therapy in the United States. Differences were observed in antibiotic expenditures when these expenditures were analyzed by location of antibiotic sales, with the majority of sales in the outpatient setting, 87% in community pharmacies.[54,55] The spread of antimicrobial resistance led to ongoing concern about such unnecessary drug use among physicians and increasingly among patients or parents and resulted in national guidelines for antimicrobial stewardship.[56]

Common pathogens such as *S. pneumoniae* and *S. aureus* typically remain treatable, but resistance in these organisms raises costs and increases the likelihood of treatment failure. Hospital-associated pathogens such as *Enterobacter, Klebsiella, Acinetobacter, Pseudomonas,* or *Enterococcus* may not be treatable with available agents.[57]

Microbial resistance is driven by antimicrobial exposure. Many studies have linked recent exposure to antimicrobial agents to an increased risk for carrying or being infected with resistant pneumococci.[58,59] During a course of prophylactic antibiotics to prevent acute otitis media, the proportion of children carrying resistant strains of pneumococci, *H. influenzae,* and *M. catarrhalis* increased, with a return to baseline levels only after the selective pressure of the antimicrobial regimen was removed.[60] Avoiding such selective pressure that drives resistance by reducing antimicrobial exposure is the focus of a variety of public health strategies to control resistance.

A set of principles from the Centers for Disease Control and Prevention (CDC) for judicious antimicrobial use in children with upper respiratory tract infections summarized scientific evidence for curtailing such use and was published as a guide to appropriate antibiotic use.[61] The CDC's current Get Smart: Know When Antibiotics Work program provides materials for healthcare professions in outpatient and inpatient settings, as well as for parents, that are designed to encourage appropriate prescribing practices (http://www.cdc.gov/getsmart/community/index.html). Programs for judicious use have been studied in private practice, managed care organizations, emergency departments, and community clinics.[62–67] Successful reductions in prescribing have been documented when groups in active intervention programs that include both physicians and patients have been compared with groups receiving no intervention other than information. Most importantly, decreased antibiotic use has not led to increased complications of "untreated infections".[62,67] Limited but convincing evidence indicates that the decrease in prescribing of antibiotics is leading to slowing of the spread of resistant bacteria.[56,66–68]

The Guidelines for Antibiotic Stewardship from the Infectious Diseases Society of America outline strategies to promote appropriate antibiotic selection and duration of therapy and evaluate the potential impact on the development of antibiotic resistance.[54] Unfortunately, few prospective, high-quality investigations specifically in children are available that document the impact of improved practices on a decrease in colonization or infection with resistant organisms.[67,68]

Mechanisms and Detection of Antimicrobial Resistance

Kevin Alby, Melissa B. Miller

Microorganisms have survived for millions of years because of their ability to adapt to hostile environments. Since the 1940s, bacteria that cause human infections have been exposed to ever-increasing antimicrobial pressure as a result of appropriate and inappropriate use of these agents. In the United States, investigators have estimated that more than 7 million pounds of antimicrobial agents are consumed annually by humans. Approximately 80% of all antibiotics sold (~29 million pounds) are used in food-producing animals in the US.[1] Although the economic benefits in agricultural use versus the risk of transfer of resistance to humans are debated, the US Food and Drug Administration (FDA) introduced the Veterinary Feed Directive to promote the judicious use of antibiotics in food-producing animals.[2–4]

Despite intensive campaigns aimed at reducing inappropriate use of antimicrobial agents, investigators have estimated that one half of all children in the industrialized world receive an antimicrobial agent annually and that three fourths of children 1 to 2 years of age receive these agents.[5–7] Although antibiotic use from 2000 to 2010 decreased 18% among children and adolescents, the prescription of broad-spectrum antibiotics increased 79%.[8] Even with continued efforts to reduce antimicrobial use in animals and humans, existing levels of antimicrobial resistance are not likely to return to the levels seen before antimicrobial abuse began.

Antimicrobial resistance exacts a high economic cost (~$60 billion annually in the US).[8] The human cost also is substantial because drug-resistant organisms frequently do not respond to therapy, thus resulting in hospitalization, surgical interventions, increasing use of diagnostic services, and death.[9] Gram-negative bacilli that produce novel β-lactamases with activity against many or, in some cases, all classes of β-lactam agents are emerging at an alarming rate and spreading globally. These include Verona-integron-encoded metallo-β-lactamase (VIM), New Delhi metallo-β-lactamase (NDM), and *Klebsiella pneumoniae* carbapenemase (KPC). An Infectious Disease Society of America initiative to have 10 new systemic drugs available by 2020 against the ESKAPE organisms (*Enterococcus faecium*, *Staphylococcus aureus*, *K. pneumoniae*, *Acinetobacter baumannii*, *Pseudomonas aeruginosa*, and Enterobacteriaceae) has spurred the development and FDA approval of new antibiotics.[10,11] Although the rate of approved antimicrobial agents is slow compared with previous decades and the challenge of developing new antimicrobial classes remains,[10] at least 39 compounds from different drug classes are in clinical trials.[12] Beyond the ESKAPE organisms, extensively drug-resistant and totally drug-resistant *Mycobacterium tuberculosis* is of global concern, especially in locales with high rates of human immunodeficiency virus (HIV) infection.[13]

Genetics of Antimicrobial Resistance

Intrinsic Resistance

Antimicrobial resistance can be attributed to intrinsic cellular properties, intrinsic mutations, acquisition of resistance genes, or intragenic recombination resulting in mosaic genes[14,15] (Table 290.1). Intrinsic resistance can be caused by inherent properties of microorganisms, such as cellular membranes, which render them resistant (e.g., gram-negative species to vancomycin). Additionally, intrinsic resistance is mediated by the mutation of chromosomal genes. Although acquired resistance mechanisms are more common, many infections are caused by 1 or few species, thus making interspecies gene acquisition difficult in vivo. In these circumstances (as postulated for both *P. aeruginosa* in the setting of cystic fibrosis and *M. tuberculosis*), the organism's primary antibiotic defense mechanism is intrinsic mutation.[16,17] Intrinsic mutations that contribute to antimicrobial resistance include variation in the antimicrobial target site (e.g., fluoroquinolones, aminoglycosides), changes in regulatory genes or promoter sequences (e.g., increase in efflux pump or inactivating enzyme expression, decrease in porin expression), and indirect mutations that affect the organism's mutation rate.[16,18]

TABLE 290.1

Common Antibacterial Drug Resistance Mechanisms

Drug Class	Resistance Mechanism	Frequency	Examples
Aminoglycosides	Enzymatic inactivation	Common	Phosphotransferases, acetyltransferases, nucleotidyltransferases in Enterobacteriaceae and *Enterococcus* spp.
	Efflux pump	Uncommon	MexX-MexY efflux pump in Enterobacteriaceae
	Altered binding site	Rare	Streptomycin-resistant *Mycobacterium tuberculosis*
	Altered uptake	Common	Streptococci and all anaerobic bacteria
β-Lactams	Enzymatic inactivation		*Staphylococcus aureus, Haemophilus influenzae,* Enterobacteriaceae
	Ambler class A β-lactamase	Common	ESBL producing: *Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis*
	Ambler class B β-lactamase	Common	VIM, IMP, and NDM carbapenemases in *Acinetobacter baumannii, Pseudomonas aeruginosa,* and selected Enterobacteriaceae; chromosomally encoded in *Stenotrophomonas maltophilia*
	Ambler class C β-lactamase	Common	AmpC chromosomal β-lactamase in *Enterobacter* spp.
	Ambler class D β-lactamase	Uncommon	Plasmid encoded in *Pseudomonas aeruginosa* and selected Enterobacteriaceae
	Altered penicillin-binding proteins	Common	Oxacillin-resistant *Staphylococcus aureus* and penicillin-resistant *Streptococcus pneumoniae*
	Efflux pump	Uncommon	MexAB-OprM pump in *Pseudomonas aeruginosa*
	Altered uptake	Uncommon	Loss of OprF and OprD in *Pseudomonas aeruginosa*

Colistin	Altered binding	Uncommon	Altered lipopolysaccharide in *Pseudomonas aeruginosa* and *Acinetobacter baumannii*
	Efflux pump and capsular overproduction	Rare	*Klebsiella pneumoniae*
Isoniazid	Altered binding	Common	Mutation of *katG* in *Mycobacterium tuberculosis*
	Overexpression of target	Uncommon	Overexpression of *inhA* in *Mycobacterium tuberculosis*
Linezolid	Altered binding	Uncommon	23s rRNA mutations or methyltransferase in *Enterococcus* spp.
Macrolides and related compounds	Efflux	Common	Macrolide resistance in streptococci
	Altered binding	Common	Methylation of 23S rRNA conferring resistance to macrolides, streptogramins, and lincosamides in *Staphylococcus* and *Streptococcus* spp.
Metronidazole	Inactivating enzyme	Uncommon	Nitroimidazole reductase in *Bacteroides* spp.
Quinolones	Altered binding	Common	Mutations in *gyr* conferring resistance in gram-negative organisms; mutations in *par* conferring resistance in gram-positive organisms
	Efflux	Uncommon	Possible in a variety of gram-negative and gram-positive organisms
	Protective protein	Rare	Protein expressed by *Klebsiella pneumoniae* that binds fluoroquinolones and thus prevents binding to target
Rifampin	Altered binding	Common	Mutations in *rpoB* gene in *Staphylococcus aureus, Mycobacterium tuberculosis,* and *Neisseria meningitides*
Tetracyclines	Efflux pump	Common	Gram-positive and gram-negative organisms
	Protective proteins	Uncommon	Gram-positive and gram-negative organisms
Trimethoprim-sulfamethoxazole	Overproduction of target	Common	Overproduction of DHFR in a variety of bacteria
	Altered binding	Common	Mutated *dhfr* gene in *Streptococcus pneumoniae*
	Bypass targeted pathway	Uncommon	Occurs in thymidine-dependent *Staphylococcus aureus*
Vancomycin	Altered binding	Common	*vanA* and *vanB* in *Enterococcus*
	Overproduction of target	Uncommon	Vancomycin-intermediate *Staphylococcus aureus*

AmpC, Ambler class C β-lactamase; DHFR, dihydrofolate reductase; ESBL, extended-spectrum β-lactamase; NDM, New Delhi metallo-β-lactamase.

Although bacteria have a low mutation rate (~10^{-8}/base pair) to preserve DNA integrity and function, naturally occurring mutations permit evolution toward fitness. Deleterious mutations also can occur, leading to loss of fitness.[19,20] Induction of a higher mutation rate (i.e., a mutator phenotype) can be beneficial to the organism, particularly when the organism is under selective pressure, such as environmental or antibiotic stress. Fluoroquinolone and aminoglycoside antibiotics can induce a hypermutable state, leading to antimicrobial resistance.[21,22] The hypermutator state is inducible or transient, and it allows for the survival and expansion of the resistant bacterial population; clinical importance requires further research.[16,23]

Acquired Resistance

Acquired resistance occurs through horizontal transfer of resistance genes among organisms by conjugation, transformation, or phage-dependent transduction; in some cases, these genes become a stable part of the recipient chromosome.[24] The 2 types of mobile genetic elements are those that move between cells and those that move within a cell. However, elements that move only intracellularly (e.g., gene cassettes, resistance transposons, integrons) can “hitch a ride” on intercellular mobile elements such as plasmids and conjugative transposons.

Plasmids consist of circular, extrachromosomal double-stranded DNA (dsDNA; ~4–400 kb) that self-replicates. A bacterium can contain multiple compatible plasmids or multiple copies of the same plasmid. Plasmid-based resistance genes can be propagated either by clonal spread of the organism or by horizontal transfer via conjugation.[24,25] Resistance genes encoding inactivating enzymes for β-lactam agents (including extended-spectrum β-lactamases [ESBLs] and carbapenemases), macrolides, aminoglycosides, and chloramphenicol; efflux genes for macrolides and tetracyclines; and altered targets for sulfonamides have been found on plasmids.[25] Plasmid-mediated resistance genes can also be located on mobile genetic elements that can relocate (either by transposition or site-specific integration) to other plasmids or chromosomes, thereby resulting in the intraspecies and interspecies spread of antimicrobial resistance.

Transposons (~2–20 kb) contain insertion sequences and a single gene or few linked genes often encoding antimicrobial resistance. In addition, transposons are flanked by inverted sequence repeats and encode for a transposase enzyme required for transposition. Conjugative transposons exist that move directly from 1 bacterium to another and have been found to mediate the transfer of resistance in gram-positive bacteria. Among the best-studied conjugative transposons are Tn*916* in *Enterococcus faecalis* encoding tetracycline resistance and Tn*1549* in enterococci encoding vancomycin resistance.[26] Nonconjugative transposons (e.g., resistance transposons) generally are transferred from cell to cell through plasmids and include Tn*1546* implicated in the transfer of vancomycin resistance from *Enterococcus* to *S. aureus*.[27]

Integrons include an integrase, mobile gene cassettes, and an integration site for the gene cassettes to allow for site-specific recombination into plasmids or the bacterial chromosome.[28] Integrons themselves are not mobile but facilitate capture of resistance gene cassettes, which subsequently insert into the chromosome. Integrons encoding antimicrobial resistance determinants have been found in certain Enterobacteriaceae organisms, as well as in *P. aeruginosa* and *Acinetobacter* species, and they are associated with resistance to β-lactams (including ESBLs), aminoglycosides, chloramphenicol, trimethoprim, and disinfectants.[25,28,29] Integrons can contain multiple gene cassettes and therefore often encode for multidrug resistance. Gene cassettes consist of a coding sequence, usually without promoter sequences, followed by an integrase-specific recombination site, and either can exist in a nonfunctional circularized form or are expressed as part of an integron or transposon.[29] More than 100 gene cassettes have been described.[30]

Mosaicism

Intragenic recombination between a sensitive locus on the host bacterial chromosome and related genes from other bacterial species can result in mosaic genes conferring antimicrobial resistance.[15] This recombination-dependent mechanism occurs primarily by direct uptake of naked DNA and is therefore limited to organisms that are naturally transformable. Some mosaic alleles, or polymorphisms, are lost or are present only in low numbers as a result of decreased bacterial fitness. However, if a mosaic allele expresses a phenotype that is favored by antibiotic-selective pressure, the mosaic likely will survive and establish a new, resistant population.[15] Examples of successful mosaicism are the penicillin-binding proteins (PBPs) in *Streptococcus pneumoniae* and the pathogenic *Neisseria* species, as well as sulfonamide-resistant dihydropteroate synthase in *N. meningitidis*.[15,31–34]

Mechanisms of Resistance

Bacteria can develop resistance to antimicrobial agents by at least 6 basic mechanisms, and multiple mechanisms can act concurrently[35]:

1. Enzymatic inactivation

2. Alteration of the antimicrobial binding site

3. Active efflux

4. Alterations in membrane permeability to prevent antimicrobial entry

5. Alterations in enzymatic pathways so that the targeted enzyme is no longer essential for organism survival

6. Overproduction of antimicrobial targets

In addition, slow rates of growth as seen in small colony variants or in organisms growing in biofilms also can contribute to resistance in vivo that is not detected readily in vitro when using standard susceptibility test methods.[36]

Aminoglycosides

Antimicrobial resistance in aminoglycosides can be either intrinsic or acquired. Intrinsic resistance is primarily caused by the inability of these molecules to accumulate in the cytoplasm where they must bind to the 30S ribosome to have an antibacterial effect, which is achieved by interfering with binding of transfer RNA (tRNA) to ribosomal RNA (rRNA) during translation and resulting in inhibition of protein synthesis.[37,38] Aminoglycosides are actively transported into the bacterial cell by a 3-step, energy-dependent process.[39] The energy necessary for this process is generated during aerobic respiration. Bacteria, when growing anaerobically, are not able to generate sufficient energy to “drive” this highly charged molecule into the cell.[39] As a result, all anaerobic organisms and those that depend on anaerobic metabolism (e.g., enterococci) are resistant to aminoglycosides.[37]

Clinically significant, acquired aminoglycoside resistance primarily is the result of acquisition of extrachromosomal elements that encode enzymes that chemically modify aminoglycosides to render them unable to bind to the ribosomal target.[28] Three major classes of enzymes inactivate aminoglycosides, and they are classified by the specific reaction catalyzed: (1) phosphotransferases (APH) that phosphorylate specific aminoglycoside hydroxyl groups, (2) acetyltransferases (AAC) that modify aminoglycosides through acetylation of selected amino groups, and (3) nucleotidyltransferase (ANT) that adenylates the aminoglycoside by adding adenosine monophosphate to selected hydroxyl groups. Resistance in clinical isolates depends on the specific inactivating enzyme produced by the organism. For example, *P. aeruginosa* can harbor 2 different types of AAC(6′): 1 type inactivates tobramycin and amikacin, whereas the other inactivates tobramycin and gentamicin.[40] Each enzyme type has variants that can inactivate each of the clinically relevant aminoglycosides. However, certain enzyme types predominate. Because of its modified chemical structure, amikacin is not inactivated by as many of these enzymes, thus resulting in a broader spectrum of activity against gram-negative bacilli compared with gentamicin and tobramycin.[38] Investigators have sought inhibitors of the transferases to allow for increased activity of aminoglycosides in resistant strains, but these studies are preliminary.[41,42] Aminoglycoside resistance is also important among gram-positive organisms (GPOs). In staphylococci, a unique bifunctional enzyme AAC(6′)-I-(APH 2″) produces modification in all 3 of the most commonly used aminoglycosides (tobramycin, gentamicin, and amikacin), with resulting resistance.[43] Although enterococci are intrinsically resistant to aminoglycosides because of impermeability, treatment with cell wall–active agents such as ampicillin or vancomycin can increase permeability and, in combination with an aminoglycoside, can result in synergistic killing.[43] Resistance secondary to impermeability is referred as “low-level” resistance (gentamicin minimal inhibitory concentrations [MICs], 16–64 μg/mL).[44] High-level resistance also occurs (gentamicin MIC >500 μg/mL), especially among vancomycin-resistant *E. faecium* strains.[44] Gentamicin resistance in enterococci reflects enzymatic inactivation, primarily the AAC(6′)-I-APH(2″) enzyme.[44] Strains producing this enzyme can be susceptible to high levels of streptomycin.

Aminoglycoside resistance resulting from efflux of aminoglycosides occurs, but it is much less common than enzymatic modification.[40] This efflux pump is a 3-component membrane structure consisting of the proteins MexX-MexY and an outer membrane protein (Opr).[45] Both OprM and OprG act as pores in the outer membrane for these efflux pumps.[46,47]

Alteration of the antimicrobial binding site as a mechanism of acquired resistance is observed infrequently, and typically it is caused by mutation. Because multiple genes encoding ribosomes are present in most bacteria, the likelihood of having the same random mutational event occurring at the same loci in multiple genes is minimal.[38] The lone exception is in *M. tuberculosis*. Because it has only a single ribosomal gene copy, ribosomal mutations can confer resistance to streptomycin.[37]

A second means of alteration of the aminoglycoside binding site has been recognized in a strain of *K. pneumoniae* that possesses a plasmid that encodes a 16S rRNA methyltransferase.[46] Modification of the 16S rRNA results in high-level resistance to gentamicin, tobramycin, and amikacin. Methyltransferase has significant sequence homology with enzymes from aminoglycoside-producing organisms, a finding suggesting that it evolved naturally for self-defense.[46] Ribosomal methylase has been found in transposons within plasmids, thus making horizontal transfer of this resistance gene likely. The 16S rRNA methyltransferase has been detected among Enterobacteriaceae, *Acinetobacter*, and *Pseudomonas*.[48–50]

β-Lactams

Resistance to β-lactam agents is caused primarily by production of β-lactamases or alteration in PBPs. In gram-negative organisms (GNOs), β-lactamase production is the more important resistance mechanism, whereas alteration in PBPs plays a central role in GPOs, including *S. aureus, S. pneumoniae,* and *Enterococcus* spp. Organisms can harbor genes simultaneously that encode both resistance mechanisms, as is seen in methicillin-resistant *S. aureus* (MRSA).[35] Organisms can express >1 β-lactamase gene as well as multiple β-lactam resistance mechanisms concurrently, including β-lactamases, β-lactam efflux, and loss of outer membrane protein porins (important in periplasmic drug accumulation in GNOs).[35]

Classification Systems for β-Lactamases

β-Lactamases are enzymes that degrade the β-lactam ring. They can be encoded chromosomally or on extrachromosomal elements. In GPOs, they are excreted into the extracellular space, whereas in GNOs they are found in the periplasmic space. The Ambler system is a common classification system that classifies the enzyme into 4 different groups (A, B, C, D), based on the enzyme structure.[51] Ambler type A, C, and D β-lactamases are classified as serine β-lactamases because they have serine at the enzyme's active site. Ambler type B enzyme is classified as a metalloenzyme because of the requirement for divalent cations, typically zinc, at the active site.[51]

Clinical Relevance of β-Lactam Resistance

The most common type A β-lactamases are TEM and SHV.[51] These β-lactamases degrade penicillin G, ampicillin, antipseudomonal penicillins, and first-generation cephalosporins. Clavulanic acid has excellent inhibitory activity against these enzymes, and organisms producing these enzymes remain susceptible to aztreonam and third-generation cephalosporins.[52] More than 180 TEM-type enzymes and 130 different SHVs have been identified.[52] TEM frequently is found in *Escherichia coli, Haemophilus influenzae,* and *Neisseria gonorrhoeae,* whereas SHV is found in a variety of Enterobacteriaceae members and *P. aeruginosa.*[52] Mutations in the region of the active site of these enzymes can expand their spectra to hydrolyze aztreonam and third-generation cephalosporins such as cefotaxime and ceftazidime. Clavulanic acid continues to inhibit these enzymes in vitro, and these organisms are still susceptible to cephamycins (cefoxitin) and carbapenems (imipenem).[52] Bacteria that are able to express this genotype are described as producing ESBLs.[52] Genes encoding ESBLs frequently are found on large plasmids, which also can encode resistance to other agents such as aminoglycosides and fluoroquinolones.[53] SHV and TEM-type ESBLs are observed most frequently in *E. coli, Proteus mirabilis,* and *K. pneumoniae,*[54] and bloodstream infections with these organisms are associated with significantly increased morbidity and mortality rates.[55]

Another important class A ESBL is CTX-M, so designated because of preferential hydrolytic activity against cefotaxime compared with ceftazidime.[56] More than 90 different types of CTX-M have been identified,[57] and CTX-M has been disseminated on plasmids to many different Enterobacteriaceae organisms, particularly to *Salmonella* strains originating in South America.[56] As with the TEM and SHV enzymes, organisms expressing CTX-M are resistant to all classes of penicillin, aztreonam, and first-, second-, and third-generation cephalosporins. Isolates expressing CTX-M remain susceptible to cephamycins and carbapenems, and like other type A ESBLs, this enzyme is inhibited in vitro by clavulanic acid and tazobactam.

The KPC enzymes are an emerging group of class A β-lactamases. Initially associated most closely with *K. pneumoniae*, plasmids encoding KPC now are found in many Enterobacteriaceae organisms. First identified in 2001,[58] KPCs are now found throughout the US. KPCs are particularly worrisome because they are capable of degrading carbapenems such as imipenem in addition to penicillins, aztreonam, and cephalosporins.[59] KPC-producing strains also can be resistant to aminoglycosides and fluoroquinolones, thus leaving few therapeutic options.[59] Traditional β-lactam–β-lactamase inhibitor combinations do not work in many KPC-expressing strains. However, newer β-lactamase inhibitors such as avibactam have shown activity against KPC-producing organisms and offer newer therapeutic options.[60]

The Ambler class B β-lactamases are enzymes that require divalent cations, typically zinc, to hydrolyze the β-lactam ring.[61] Class B β-lactamases are capable of hydrolyzing most β-lactam containing antibiotics including carbapenems and are inhibited by chelating agents such as ethylenediaminetetraacetic acid (EDTA) but not by traditional β-lactamase inhibitors. Aztreonam alone among the β-lactams can retain some activity against isolates expressing these enzymes.[62] The class B enzymes can be chromosomally encoded, as is seen with *Stenotrophomonas maltophilia,* or they can be transferred by plasmids, transposons, or integrons. The most commonly encountered transferable metallo-β-lactamases are IMP and VIM.[61] Metallo-β-lactamase–producing isolates also frequently are resistant to fluoroquinolones and aminoglycosides.[61] IMP is found most commonly in *P. aeruginosa* and *A. baumannii* but also can be found in Enterobacteriaceae, particularly *Serratia marcescens,* and other *Pseudomonas* species. VIM is primarily found in *P. aeruginosa* but has been reported in Enterobacteriaceae and *Acinetobacter*.[61] The emergence of the New Delhi metallo-β-lactamase (NDM) is of significant concern.[63,64] NDM-producing strains are resistant to all antibiotics except tigecycline and colisitin.[64] First seen in the United Kingdom in 2008, NDMs are now the most common carbapenemase-producing organisms recovered clinically in the UK.[64] Further, NDMs now have been found in the US,[63] as well as throughout the Pacific.

The Ambler class C β-lactamase is referred to as AmpC. AmpC can be chromosomally or plasmid encoded. Chromosomally encoded AmpC β-lactamases typically found in *Enterobacter* and *Serratia*, are inducible, and result in low-level resistance to ampicillin, cefazolin, and cefoxitin.[65] Induction by cephamycin or carbapenems can result in high-level resistance to penicillin and first-, second-, and third-generation cephalosporins. AmpC is not inhibited by clavulanic acid.[52] Plasmid-encoded AmpC was first reported in *K. pneumoniae.* Plasmids carrying AmpC often carry resistance genes for a variety of antibiotics including aminoglycosides, fluoroquinolones, trimethoprim, and tetracylines.[65] Such organisms have constitutive AmpC production and as a result typically are resistant to penicillins, including those used in combination with β-lactamase inhibitors, as well as first-, second- and third-generation cephalosporins.[65] Some, but not all, also are resistant to monobactams. Carbapenems are not well degraded by AmpC and remain a therapeutic option, although isolates with mutation in outer membrane porins can be resistant.[65] Newer agents, specifically ceftolozane and tazobactam, have been developed that retain activity against organisms with AmpC enzymes even with changes in porin permeability or efflux pumps.[66]

The prototypic Ambler class D β-lactamase is the OXA family, so designated because of higher rate of hydrolysis of oxacillin compared with benzylpenicillin.[67] Some OXA enzymes exhibit carbapenemase activity, although this activity may not confer resistance in vivo.[67] Most OXA enzymes are resistant to β-lactamase inhibitors, although avibactam has demonstrated activity against

OXA-48.[68,69] Plasmid-encoded ESBL OXA enzymes have been found in *P. aeruginosa*.[70] However, the most clinically important OXA-carbapenemase–producing organism are *Acinetobacter* organisms.[71] In *Acinetobacter*, OXA-carbapenemases can be encoded chromosomally or on plasmids. Such *Acinetobacter* organisms are resistant to penicillins, first-, second-, and third-generation cephalosporins, cefepime, and carbapenems. These isolates also are resistant to aminoglycosides and fluoroquinolones.[71] Since the mid-2000s, OXA-carbapenemase–producing *Acinetobacter* has spread globally and has caused nosocomial outbreaks in numerous facilities.[71]

The most clinically relevant β-lactamase among GPOs is Ambler class A penicillinase- producing *S. aureus*, rendering resistance to β-lactams. Semisynthetic penicillins such as methicillin, oxacillin, nafcillin, and others were developed that were poorly hydrolyzed by the *S. aureus* penicillinase, thus maintaining clinical activity. Resistance soon developed in *S. aureus* to penicillinase-stable penicillins as a result of alteration at the specific PBP2 target site. This modified PBP, designated PBP2a, has low affinity for almost all β-lactam antimicrobial agents, with the exception of ceftaroline.[72] PBP2a is primarily encoded by the *mecA* gene, and strains that contain *mecA* are designated as MRSA. Healthcare-associated MRSA (HA-MRSA) arose and frequently was resistant to other agents, including aminoglycosides, macrolides, and fluoroquinolones.[72,73] In the late 1990s, community-associated MRSA (CA-MRSA) appeared, differing from HA-MRSA. CA-MRSA strains, although resistant to β-lactams and containing *mecA*, frequently remain susceptible to other classes of antibiotics.[74] The *mecA* encoding region, called the staphylococcal chromosomal cassette (SCC) *mec* type IVa, in CA-MRSA tends to be much smaller than the SCC most commonly encountered in HA-MRSA and does not contain genes for resistance to other agents.[75] The distinction between HA-MRSA and CA-MRSA has become less clear and less relevant because "CA-MRSA" is now found routinely in the healthcare setting.[76] Newer mechanisms of methicillin resistance, such as those encoded by a *mecA* homologue, *mecC*, will be important to observe because they may not be detected by current targeted methods (*mecA* polymerase chain reaction [PCR], PBP 2a detection).[77]

With the redefining in 2008 of penicillin resistance for *S. pneumoniae* for nonmeningeal isolates from a penicillin MIC ≥2 to ≥8 μg/mL, and for meningeal isolates to penicillin MIC ≥0.12 μg/mL, restatement of the epidemiology of drug resistance among pneumococci is necessary.[78] Most isolates with penicillin MIC 2 to 4 μg/mL generally are susceptible to third-generation cephalosporins but frequently are resistant to other classes of antimicrobial agents, including macrolides, sulfonamides, and tetracycline.[79] Isolates with penicillin MIC ≥8.0 μg/mL frequently are resistant to third-generation cephalosporins.[80] Penicillin resistance is caused by alterations in PBP2x, 2b, and 1a that result in reduced binding of β-lactams coupled with increased production of branched-structure muropeptides.[81,82] Resistance is believed to be encoded by mosaic PBP genes that were transferred to *S. pneumoniae* from commensal respiratory tract streptococci by transformation and recombination.[32]

Penicillins, specifically ampicillin, are the drugs of choice for treating enterococcal infections,[72] but resistance to cell wall–active agents, β-lactams, and vancomycin is common, especially among isolates of *E. faecium*.[72] Intrinsically resistant to cephalosporins and aminoglycosides, enterococci have acquired resistance to both ampicillin and vancomycin.[83] β-Lactamase does not play a role in ampicillin resistance of *E. faecium*.[84] Alteration in PBP5 may be responsible for low-level ampicillin resistance, but assigning it a role in high-level resistance has proven problematic.[84]

β-Lactam resistance among *Haemophilus influenzae* organisms can be caused by β-lactamases or modification in PBP3, so-called β-lactamase negative ampicillin resistant (BLNAR) strains.[85–87] Infrequently, strains are identified that produce β-lactamase and also have altered PBP3.[87] Strains are resistant to ampicillin–β-lactamase inhibitor agents.[86,87] β-Lactamases of *H. influenzae* are Ambler type A, and the encoding genes are found on plasmids.[87] A survey of 6642 *H. influenzae* isolates collected globally identified 25% producing β-lactamase and 1% with altered PBP.[85] However, certain geographic “hot spots” (e.g., Japan and Spain) have higher rates of resistance because of PBPs.[86,88]

Colistin

Although it can be nephrotoxic, colistin use is re-emerging because of the increasing number of multidrug-resistant (MDR) gram-negative bacilli. Colistin has been used intravenously, or by aerosol in the case of *P. aeruginosa* exacerbations in cystic fibrosis.[89] However, colistin resistance is described, and some bacteria are intrinsically resistant to colistin, including all GPOs, all anaerobic bacteria, and selected gram-negative bacilli, including *Burkholderia cepacia* complex, *Morganella, Proteus, Providencia,* and *Serratia* spp.[90,91]

Colistin, a positively charged polypeptide of the polymyxin family, electrostatically interacts with the negatively charged lipid A component of lipopolysaccharide (LPS) in the outer membrane of GNOs. The drug also causes damage to the cytoplasmic membrane, thus resulting in permeability changes, leakage of cellular material, and ultimately cell lysis and death.[89]

Although reported, development of colistin resistance is uncommon, and transmission of resistance by extrachromosomal elements has not been recognized. Three main mechanisms of resistance are known: (1) LPS modifications that decrease the negative charge of LPS and therefore lower drug binding affinity, (2) overexpression of efflux pump systems, and (3) overproduction of capsular polysaccharide.[90] The 2-component regulatory systems PmrA-PmrB and PhoP-PhoQ are important in the development of colistin resistance, primarily by constitutively activating LPS-modifying genes.[91] Mutations in any of the first 3 genes of the lipid A biosynthesis pathway (*lpxA, lpxC,* and *lpxD*) have also been shown to confer colistin resistance in *A. baumannii.*[92] Efflux pump systems AcrAB and KpnEF and upregulation of capsule biosynthesis contribute to colistin resistance in *K. pneumoniae*.[91] Colistin heteroresistance has been described in *A. baumannii,* but the molecular mechanism and the clinical significance of these strains remain to be determined.[91,93]

Daptomycin

Daptomycin is an acidic cyclic lipopeptide antibiotic that acts in a calcium-dependent manner to disrupt the cell membrane potential and therefore its permeability. The exact mechanism of bacterial killing is unclear, but daptomycin appears to insert into phosphatidylglycerol-rich membrane at the cell division septum.[94]

Daptomycin also may act on a sensor kinase (YycG) localized at the cell septum, thus leading to rapid cell death without lysis by interfering with the YycF-YycG 2-component signal transduction cascade.[94] A clinical pair of *E. faecalis* isolates (before and after development of daptomycin resistance) was compared using whole genome sequencing, and 3 mutated genes were identified: (1) *cls*, (2) *gdpD*, and (3) *liaF*.[95] The first 2 genes are involved in phospholipid metabolism, and the third is a member of a 3-component regulatory system (LiaFSR) involved the stress-sensing response of the cell envelope to antibiotics.[96] Similarly, a clinical pair of susceptible and resistance *E. faecium* strains was genetically compared, and mutations in 8 genes were identified, including 2 genes involved with phospholipid metabolism and *yycG*.[97]

In *S. aureus*, daptomycin resistance appears to result from an increase in cell surface charge such that the positively charged drug is repelled from the cell surface.[96] Stepwise mutations in several genes (including *mprF*, *yycG*, *rpoB*, and *rpoC*) have been associated with decreased susceptibility to daptomycin, likely through effects on the cell wall or membrane.[98,99] Combined mutations, more so than single mutations, are associated with higher MICs. Although most vancomycin-intermediate *S. aureus* and all vancomycin-resistant *S. aureus* strains maintain daptomycin susceptibility, a correlation exists between thickness of the *S. aureus* cell wall and nonsusceptibility to daptomycin (see the later discussion of vancomycin).[100]

Glycopeptides

Glycopeptide antibiotics inhibit peptidoglycan synthesis in the cell walls of GPOs. Formerly, teicoplanin (primarily used outside of the US) and vancomycin were the only glycopeptide antibiotics. Now, lipoglycopeptides (dalbavancin, oritavancin, and telavancin) have been added to the antimicrobial armamentarium. Most of our knowledge of glycopeptide resistance comes from clinical and laboratory studies with vancomycin. Increased use of vancomycin (as oral therapy for *Clostridium difficile* colitis, as treatment for MRSA and penicillin-resistant *S. pneumoniae* infections, and the increase in glycopeptide use in animal husbandry) has been associated with increasing resistance among GPOs.[101]

Vancomycin binds to the D-Ala-D-Ala C-terminus of peptidoglycan precursors, thereby blocking their addition to the growing peptidoglycan chain and preventing the subsequent transglycosylation and transpeptidation steps of cell wall biosynthesis. Because vancomycin must penetrate the peptidoglycan to reach its target, and many D-Ala-D-Ala residues are present in the cell wall, vancomycin is a relatively inefficient drug at obtaining high concentrations around its real targets because drug molecules also become bound by false targets in the peptidoglycan.[102] This phenomenon contributes to slow bactericidal activity. Mechanisms of vancomycin resistance identified to date are target modification, removal of susceptible target, and decreased permeability secondary to cell wall changes.[27,103]

In enterococci, the *van* genes encode the resistance phenotype. Several *van* genes (*vanA, B, C, D, E, F, G, L, M, N)* have been described and are characterized by high MIC values of vancomycin and teicoplanin, transferability, genetic location in the bacterial host (chromosome versus transposon or plasmid), inducible or constitutive expression, and the modified target produced.[27,104] The most clinically relevant *van* genes remain *vanA* and *vanB* which confer high-level inducible resistance (MIC ≥64 μg/mL) in *E. faecium* and *E. faecalis.* The *vanA*-containing organisms are by far the most common in both Europe and the US. The *vanA* and *vanB* operons can be located on transposons, which are transferable by plasmids or large, mobile chromosomal elements.[27] The transferability of *vanA* and *vanB* genes is the basis for infection control measures to monitor and prevent the spread of vancomycin-resistant enterococci (VREs). The *vanA* and *vanB* genes encode ligase enzymes that change the acyl-D-Ala-D-Ala C-terminus of lipid II peptidoglycan precursors to acyl-D-Ala-D-Lac (lactate). This altered ligation results in the alteration of the binding site of vancomycin and thus ~1000-fold lower affinity for its target.[105] The enzymes are regulated in an operon by a 2-component sensor kinase and response regulator pair (VanR-VanS) that responds to environmental stimuli and mutations and is responsible for inducible and constitutive resistance phenotypes.[106]

Low-level resistance (MIC, 2–32 μg/mL), found in *Enterococcus gallinarum, E. casseliflavus,* and *E. flavescens,* is encoded by the *vanC* genes (*vanC1, vanC2, vanC3,* respectively). Substituting acyl-D-Ala-

D-Ala with acyl-D-Ala-D-Ser results in an approximately sixfold lower affinity of vancomycin for its peptidoglycan precursor target.[107] Unlike *vanA/B*, *vanC* genes are encoded chromosomally and are nontransferable. Therefore, *vanC*-containing species are not considered “true” VREs for infection control purposes.

Vancomycin resistance can occur in *S. aureus*, including vancomycin-resistant *S. aureus* (VRSA; MIC ≥16 μg/mL) and vancomycin-intermediate *S. aureus* (VISA; MIC, 4–8 μg/mL). First isolated in 2002, VRSA has been confirmed 13 times in the US.[108] All VRSA strains tested carry the *vanA* ligase gene, likely originating from a coinfecting or colonizing VRE. Risk factors of patients with VRSA infections include older age, compromised blood flow to lower limbs, chronic ulcers, a history of vancomycin therapy, and concomitant or previous isolation of MRSA or VRE, or both.[109,110] To date, VRSA has not been found in children.[111] VRSA strains have high MIC values and are detectable readily by routine antimicrobial susceptibility testing; VISA strains have lower MICs, are heterogeneous, and are more difficult to detect.

The mechanism of resistance for VISA strains appears to be a thickened cell wall; VISA isolates do not carry *van* genes.[104] VISA isolates typically have multiple metabolic mutations,[102,112] but the only strict correlation with the VISA phenotype is a thickened cell wall, as shown by electron microscopy.[113] This thickened cell wall, which acts to sequester or “clog” vancomycin in the peptidoglycan, is postulated to reduce susceptibility.[102,114] Some populations of *S. aureus* contain daughter cells that show increased vancomycin MICs of 1 to 4 μg/mL; this type is referred to as heteroresistant (or heterogeneous) VISA (hVISA). Although still “susceptible,” hVISA subpopulations can proliferate and become the dominant clone under the selective pressure of vancomycin use.[114] Stepwise mutations in certain loci (i.e., the 2-component systems GraR-GraS and VraR-VraS) can lead to an hVISA phenotype and then to a true VISA phenotype.[112] Compared with patients with MRSA bloodstream infections, patients with hVISA infections have been reported to have more days of bacteremia, higher rates of endocarditis and osteomyelitis, and higher rates of vancomycin treatment failure, but no difference in mortality rates.[115] The prevalence and clinical impact of the hVISA phenotype are still largely unknown because detecting hVISA can be difficult and is not routinely done by clinical laboratories.[112]

Certain GPOs are intrinsically resistant to vancomycin, including *Erysipelothrix*, *Leuconostoc, Pediococcus*, and *Lactobacillus*.[116] Although these organisms' peptidoglycan precursors end in D-Ala-D-Lac, their genomes do not appear to contain genes homologous to enterococcal *van* genes.[117] *Leuconostoc* D-Ala-D-Lac ligases appear to have evolved independently from the enterococcal *van* ligases, perhaps because of the abundance of lactate in the environment for these organisms.[117] The mechanism of vancomycin resistance in *Erysipelothrix* is unknown.

Like the glycopeptides, the lipoglycopeptides (dalbavancin, oritavancin, and telavancin) have a heptapeptide core, but these drugs have lipophilic side chains that provide additional antimicrobial activity when compared with vancomycin. In addition to inhibiting peptidoglycan synthesis, telavancin and oritavancin disrupt membrane integrity and increase permeability; oritavancin also inhibits RNA synthesis.[118] The *vanA* gene confers resistance to dalbavancin and telavancin, but not to oritavancin. All the lipoglycopeptides maintain activity against *vanB*-containing VRE. Additionally, all lipoglycopeptides have activity against VISA, but only oritavancin is active against VRSA.[118]

Isoniazid

Isoniazid (INH) inhibits a specific enzyme, InhA, in the synthetic pathway of mycolic acid, a key component of the cell wall of *M. tuberculosis*. To be active, INH must first be modified to its active form, a hydrazine derivative, by catalase produced by the organism.[119] Mutation in the catalase gene, *katG,* or genetic inactivation of the gene prevents formation of the hydrazine derivative and results in INH resistance. Approximately 42% to 58% of INH-resistant strains have alterations in *katG*.[119] Multiple mutations or stop mutations are associated with higher levels of resistance.[120] A second resistance mechanism, a specific mutation in the *inhA* regulatory region that causes overexpression of inhA, results in low-level INH resistance.[119] Up to 30% of INH-resistant *M. tuberculosis* isolates do not have mutations in *katG* or *inhA*.[121,122] Although mutations in *ndh* (reduced nicotinamide adenine dinucleotide [NADH] dehydrogenase), *kasA* (β-ketoacyl acyl-carrier-protein [ACP] synthase), and *ahpC* (alkyl hydroperoxide reductase and its promoter) have been described in INH-resistant strains, further validation of clinical relevance is needed.[119,123]

Macrolides and Related Compounds

Macrolides and related compounds act on the 50S ribosomal subunit by binding the peptidyltransferase region and stimulate the premature dissociation of peptidyl-tRNA from ribosomes. These antibiotics are primarily bacteriostatic because they inhibit protein synthesis and include macrolides, lincosamides, streptogramins, and ketolides. Resistance occurs by alteration of target, active efflux, and antibiotic inactivation.[124] Macrolide resistance can occur as selective resistance to the 14- and 15-membered macrolides (erythromycin, clarithromycin, azithromycin) but not to 16-membered macrolides (spiramycin, josamycin), lincosamides (clindamycin), or streptogramin B (M phenotype); or it can occur as resistance to all of the foregoing (MLS_B phenotype). M-type resistance generally confers low-level resistance among streptococci (MICs 1–32 μg/mL), whereas MLS_B resistance commonly confers high-level resistance (MICs >256 μg/mL). The bactericidal streptogramins (i.e., quinupristin-dalfopristin) and the bacteriostatic ketolides (i.e., telithromycin) have activity against MLS_B-resistant organisms.

MLS_B resistance is caused by methylation of the 23S rRNA, which blocks the ribosomal binding site (RBS) for macrolides, lincosamides, and streptogramin B. The methylase is encoded by *erm* (erythromycin ribosome methylase) genes and dimethylates adenine at position 2058, a process that prevents access to the target either directly or by conformational change.[124] The MLS_B phenotype can be constitutive or inducible (MLS_B-C or MLS_B-I, respectively). For MLS_B-I strains, *erm* mRNA is inactive in the absence of an inducing macrolide such as erythromycin. Through studies in *S. aureus,* the mechanism of inducibility has been shown to be stem-loop secondary structures in the 5′ *erm* mRNA regulatory region that sequester the RBS.[125] In the presence of low concentrations of erythromycin (the inducer), ribosomes stall in the *erm* regulatory region, with resulting dissociation of stem-loop structures that subsequently permits unmasking of the RBS, translation of the *erm* methylase, and the resistant phenotype. Numerous reports have noted failed clindamycin therapy for MLS_B-I infections, with postulated microbial conversion from the MLS_B-I to the MLS_B-C phenotype.[125,126] Target alteration by mutations in L4 or L22 ribosomal proteins of the 50S subunit also has been described. These mutations can impair passive transport through the nascent peptide exit tunnel of the ribosome and distort the erythromycin binding site.[127] In *Mycoplasma pneumoniae* and *N. gonorrhoeae,* macrolide resistance is caused by mutations in the 23S rRNA gene.[128,129]

M-type resistance is primarily associated with an active efflux system driven by proton motive force.[130] Chromosomally located macrolide efflux (*mef*) genes have been found in numerous bacterial genera, including *Streptococcus, Enterococcus, Staphylococcus, Granulicatella, Gemella, Neisseria,* and *Bacteroides* species,[131] and plasmid-encoded efflux genes (*msrA*) have been identified in *Staphylococcus* species.[132] In pneumococci, the *mef* gene is located on a transposon that can be transferred horizontally.[133] Highly resistant *S. pneumoniae* isolates that harbor both *erm* and *mef* resistance mechanisms are reported increasingly.[134]

Macrolide resistance secondary to drug inactivation rarely is found in clinical isolates and is found more commonly in macrolide-producing organisms as a survival mechanism.[135] *S. aureus* produces a phosphotransferase that inactivates macrolides but not lincosamides and is encoded by the *mphC* gene.[136] Nucleotidyltransferases encoded by *lnuA/linA* and *lnuB/linB* have been found in staphylococci and enterococci, thus resulting in inactivation of lincosamides, but not macrolides.[136]

Metronidazole

Metronidazole has bactericidal activity against a broad spectrum of anaerobic bacteria and selected protozoans. Metronidazole is a prodrug that is reduced in the cytoplasm by a nitroreductase enzyme; resulting toxic intermediates disrupt nucleic acid structure. This drug is particularly useful in treating mixed anaerobic infections in which *Bacteroides* or *Prevotella* spp. predominate and is a widely used therapy for *C. difficile* infection.[137,138] In a US survey of

Bacteroides, metronidazole resistance was found in <1% of isolates.[139]

Metronidazole resistance mechanisms have been best described in *Bacteroides* spp. Resistance results from activity of the enzyme nitroimidazole reductase, which catalyzes the conversion of 4- or 5-nitroimidazole to 4- or 5-aminoimidazole. The enzymatic modification prevents the formation of toxic drug intermediates, the active form of metronidazole.[140] This enzyme is encoded on the *nim* gene, has 7 variants described, and can be encoded chromosomally or on plasmids.[141] This gene has been found in *Bacteroides, Helicobacter,* and *Prevotella*.[142,143]

Clinical resistance to metronidazole among *C. difficile* and *Helicobacter pylori* is well documented, although demonstration in vitro and understanding of the mechanism have proved difficult.[144,145] Emerging data suggest that efflux pumps also may play a role in metronidazole resistance among *Helicobacter* organisms.[145] Heteroresistance to metronidazole was described in 1 study in approximately 6% of *C. difficile* isolates directly isolated from clinical specimens.[144] This phenotype, however, is unstable. The mechanism of metronidazole resistance or clinical failure for *C. difficile* currently is unknown. *C. difficile* does not harbor *nim*.[144,146]

Oxazolidinones

Linezolid and the more recently FDA-approved tedizolid belong to the oxazolidinone class of antimicrobial agents. The oxazolidinones bind to the 50S ribosomal subunit and prevent the formation of a functional 70S-initiation complex, which is essential to bacterial protein translation. Even with increasing use, oxazolidinone resistance is uncommon. Worldwide surveillance data from 2004 to 2013 indicate that the incidence of linezolid resistance is 0.7% to 1.2% for vancomycin-resistant enterococci, <0.1% to 0.3% for vancomycin-susceptible enterococci, and <0.1% for *S. aureus*.[147] US and European surveillance data show that, based on MIC_{90} values, tedizolid is fourfold more potent than linezolid against gram-positive isolates, including MRSA and VRE; 99.8% of isolates tested were susceptible.[148]

The primary mechanism of oxazolidinone resistance is specific nucleotide substitutions in the 23S rRNA binding site, although mutations also have been described in ribosomal proteins L3 and

L4.[149] Chromosomal mutations usually occur after prolonged linezolid exposure,[150] but they have been described in linezolid-naïve patients.[151] A clear association exists between the number of 23S rRNAs that are mutated and MIC values,[152,153] as well as possibly between the number of mutated 23S rRNAs and length of linezolid exposure.[154] Linezolid resistance also can be secondary to acquisition of the plasmid-encoded *cfr* gene encoding a 23S rRNA methyltransferase, which alters the target site and confers resistance to other antibiotics but does not appear to cause tedizolid resistance.[149,155] A plasmid-encoded ABC (adenosine triphosphate–binding cassette) transporter gene (*optrA*) was found to be associated with oxazolidinone and phenicol resistance in a clinical isolate of *E. faecalis*.[156]

Quinolones

Ciprofloxacin reportedly is the most consumed antibacterial agent worldwide,[157,158] and it also has widespread use in animals. Multiple resistance mechanisms exist: mutations in target enzymes, changes in intracellular drug concentrations by altered entry and efflux, modification of the drug by bacterial enzymes, and inhibition protection of target enzymes. Quinolones and subsequent derivatives such as the fluoroquinolones act by binding to enzymes that are essential for bacterial replication, transcription, recombination, and DNA repair: DNA gyrase and topoisomerase IV.[159] These enzymes make dsDNA breaks in the chromosome and introduce negative DNA supercoils to allow subsequent activities such as replication. Quinolones trap and release this dsDNA break intermediately, thus resulting in activation of the stress (SOS) response and ultimately cell death.

Gyrase and topoisomerase IV have 2 pairs of subunits (A and B). The primary quinolone target appears to be gyrase A (*gyrA*) in GNOs and topoisomerase IV subunit A (*parC*) in GPOs.[158] A first-step *gyrA* mutation results in low-level resistance to fluoroquinolones. When a second mutation occurs either in *gyrA* or in another quinolone target such as *parC,* high-level resistance to the fluoroquinolones occurs. The same phenomenon has been demonstrated in GPOs, with the first-step mutation generally occurring in *parC.*

Once the primary mutation occurs in either *gyrA* or *parC* (and, more rarely, the B subunit genes, *gyrB* or *parE*), additional mechanisms of resistance can contribute to high-level fluoroquinolone resistance other than secondary mutations in gyrase and topoisomerase IV genes. These mechanisms include altered permeability and efflux. Altered permeability in the absence of other mutations causes low-level resistance and contributes to quinolone resistance in GNOs,[160] and it is mediated by decreased expression of outer membrane porins or alterations in LPS composition that decrease drug entry into cells.[158] Additionally, resistance can arise from increased efflux. Given their nonspecific nature, many of the efflux pumps require overexpression to result in the quinolone-resistant phenotype.

All the foregoing quinolone resistance mechanisms are chromosomally encoded, indicating that quinolone resistance is spread by clonal expansion. Although gyrase and topoisomerase gene mutations are the main mechanisms of quinolone resistance, multiple resistance mechanisms encoded on plasmids can contribute.[161] The Qnr determinant is located on a plasmid-encoded integron, first described in *K. pneumoniae* and subsequently in *E. coli* and *Enterobacter cloacae*.[159,162–164] The Qnr protein binds and protects DNA gyrase and topoisomerase IV from inhibition by ciprofloxacin.[163] As in first-step *gyrA* mutations, Qnr causes low-level resistance only in the absence of other resistance mechanisms. Commonly, *qnr*-containing plasmids also encode for an AmpC or ESBL.[165,166]

Rifampin

Rifampin targets the β-subunit of bacterial DNA-dependent RNA polymerase encoded by the gene *rpoB*. Point mutations in *rpoB* can result in amino acid substitutions, decreased binding, and resistance.[167] Because point mutations can result in high-level resistance, rifampin is rarely used alone, to prevent emergence of resistance. Mutations in *rpoB* have been detected in a variety of bacteria, notably in *S. aureus*,[168] *N. meningitidis*,[169] and *M. tuberculosis*.[167] In *M. tuberculosis*, most rifampin-resistant mutations occur in the 81-base pair rifampin-resistance determining region (RRDR) of *rpoB*. Sequencing the RRDR resulted in 97.1% sensitivity and 93.6% specificity when compared with routine antituberculosis drug susceptibility testing.[170] Three mutations (*Ser531Leu*, *His526Tyr*, and *Asp516Val*) accounted for 75% of the rifampin resistant isolates.[170] Other mechanisms of resistance to rifampin including rifampin modifying enzymes and efflux pumps are found in environmental GPOs such as *Nocardia* and *Mycobacterium* and in gram-negative bacilli such as *S. maltophilia* and *Burkholderia cenocepacia.* Clinical significance of these mechanisms compared with *rpoB* mutations is minor.[171] Although further investigation is required, efflux pumps have also been described that may be responsible for low-level rifampin resistance in *M. tuberculosis*.[172]

Tetracyclines

Tetracyclines have been in use since the 1950s for the broad-spectrum treatment of infections with GNOs and GPOs, including intracellular pathogens such as *Chlamydia, Rickettsia,* and *Mycoplasma.* Widespread use of tetracyclines since the 1950s as therapeutic agents in adults, as a growth promoter in both animals and plants, and as longterm subtherapeutic treatment of noninfectious conditions has led to substantial resistance.[173] Tetracycline resistance mechanisms have been identified in >75 bacterial genera.[174,175] Doxycycline, minocycline, and a minocycline-derived glycylcycline, tigecycline, are used most frequently.[176] Tigecycline has the same mode of action as other tetracyclines, but it is active in the presence of tetracycline resistance genes as a result of steric hindrance introduced by an additional side chain.[177] Expression of resistance-nodulation-division (RND)-type efflux pumps leads to intrinsic resistance to tigecycline in *Pseudomonas* and *Proteus* spp.[178]

Tetracyclines are bacteriostatic, reversibly inhibiting protein synthesis by binding to the 30S ribosome and preventing elongation by inhibiting tRNA association. Intrinsic resistance typically is mediated by dysregulation of transcription that affects both influx and efflux of the drug.[179] Acquired resistance is most commonly caused by the acquisition of genes that encode tetracycline-specific efflux pumps and ribosomal protection proteins. These genes often are located on mobile elements, including plasmids, transposons, and integrons.[173] Most of the efflux genes are found only in GNOs, but 2 (*tetK* and *tetL*) are found primarily in GPOs. All these genes except *tetB* confer resistance to tetracycline and doxycycline; *tetB*-containing isolates also are resistant to minocycline, but not to tigecycline. However, in vitro mutations in *tetA* and *tetB* have been produced that result in tigecycline resistance.[180] The genes that encode ribosomal protection proteins confer resistance to tetracycline, doxycycline, and minocycline, with *TetO* and *TetM* the most widely distributed determinants. Bearing sequence similarity to translation elongation factors, ribosomal protection proteins appear to be ribosome-binding guanosine triphosphatases that dislodge tetracycline from the ribosome.[175,181,182] The ribosomal protection proteins are found in a variety of bacteria, including GPOs, nonenteric GNOs, and anaerobic bacteria, and they often are linked to other resistance genes, such as *erm*.[173,181]

Trimethoprim-Sulfamethoxazole

Although no longer recommended for treatment of otitis media,[183,184] trimethoprim-sulfamethoxazole (TMP-SMX) has broad use, such as for treatment of skin and soft tissue infection with CA-MRSA.[185]

TMP-SMX acts by inhibiting 2 steps in bacterial folic acid synthesis. Sulfamethoxazole inhibits dihydropteroate synthetase and blocks the formation of dihydrofolate, whereas trimethoprim inhibits dihydrofolate reductase (DHFR) and blocks the formation of tetrahydrofolate. Bacteria can develop resistance to either component of TMP-SMX. Intrinsic resistance is recognized in *Bacteroides, Neisseria,* and *Clostridium* species as a result of poor TMP binding to DHFR molecules.[186] Additionally, organisms such as *Enterococcus* and *Lactobacillus* are capable of using extracellular folate and thus bypassing the targeted pathway.[187] Acquired TMP resistance can be secondary to overproduction of DHFR caused by a mutation in the promoter region controlling its synthesis or by mutations in the *dhfr* gene that result in decreased binding.[186] In *S. pneumoniae,* mutation in the *dhfr* gene resulting in reduced TMP binding plays a central role in TMP-SMX resistance; resistance can be transferred to other strains of pneumococci by transformation.[188] Resistance to SMX is caused by alteration in its target, dihydropteroate synthetase, through point mutation or acquisition of extrachromosomal elements.[186]

Detection of Antimicrobial Resistance

Antimicrobial resistance can be detected using techniques that rely on either phenotypic characteristics of an organism or detection of genetic changes (i.e., gene acquisition or mutation) that predict resistance. Phenotypic antimicrobial susceptibility testing in vitro predicts clinical resistance (i.e., identifying antimicrobial agents that will be ineffective) more accurately than it does therapeutic effectiveness (in vitro susceptibility).[189] Besides intrinsic antimicrobial activity, therapeutic effectiveness depends on multiple factors, such as the following: the site of infection, penetration of the agent, and local environmental conditions such as pH and oxygen tension; the mode of growth of the organism (planktonic vs. biofilm); the pharmacokinetics of the agent and the dosing regimen used; the immune status of the patient; and adherence to the antimicrobial regimen.[189]

Establishment of Breakpoints

Three types of breakpoints (or cutoffs) are used to describe the susceptibility of a specific organism against a specific drug. These data are analyzed and published by 3 major groups: the FDA, the Clinical and Laboratory Standards Institute (CLSI), and the European Committee on Antimicrobial Susceptibility Testing (EUCAST). These organizations do not have complete harmonization of choices for breakpoints. First, the microbiologic breakpoint (also called wild-type breakpoint or epidemiologic cutoff) is determined by comparing the MIC of a specific drug for bacterial isolates with no known resistance to the MICs obtained for organisms with known resistance mechanisms.[190] A bimodal distribution pattern is generally observed in which the drug is highly active (low MICs) against the “susceptible” organisms and has poor activity (high MICs) against the “resistant” organisms. Some antimicrobial agents lack a clear bimodal distribution (e.g., polymyxins); newly developed drugs may not have a testable resistant population to permit characterization (e.g., daptomycin). Second, the clinical breakpoint is determined by assessing the MICs for strains that are likely to be treated with the agent with clinical success versus strains associated with clinical failure. These data are generated by prospective human clinical trials.[190] Third, the pharmacokinetic and pharmacodynamic (PK/PD) breakpoint of a particular drug (usually in serum, but occasionally in other body compartments such as the central nervous system or urinary tract) is determined by mathematically extrapolating animal model data to humans.[190] Ideally, the published breakpoint that is used by clinical laboratories is set using a combination of the 3 types of breakpoint data described earlier. Susceptibility testing should not be performed when susceptibility (penicillin for *Streptococcus pyogenes*) or resistance (vancomycin for Enterobacteriaceae) is predictable. Susceptibility testing also should not be performed when in vitro activity is known not to correlate with therapeutic efficacy (cephalosporins for *Listeria monocytogenes*).[191]

Methods of Susceptibility Testing

The reference method or gold standard for phenotypic susceptibility testing is MIC determination (see Chapter 286). Depending on the organism, testing can be done by either broth microdilution or agar dilution.[191] Automated commercial test systems, such as Vitek (bioMérieux, Durham, NC), Phoenix (BD Bioscience, Sparks, Md), and MicroScan (Beckman Coulter, Brea, Calif), which employ modification of these methods, are used widely. These systems are fast, mechanically reliable, and highly reproducible; they offer significant cost efficiencies (including interfacing with clinical information systems) and combine susceptibility testing and organism identification in a single system. Automated susceptibility testing, however, is not as accurate as reference methods, particularly for detecting inducible resistance and other emerging resistance.[192] Software changes are introduced to address problems, but organisms evolve to develop resistance faster than changes can be developed and validated. Perpetually, systems may be a step behind. For example, in mid-2010, the CLSI lowered carbapenem susceptibility breakpoints for meropenem and imipenem fourfold (from ≤4 μg/mL to ≤1 μg/mL) because some carbapenemase-producing Enterobacteriaceae organisms have carbapenem MICs as low as 0.125 μg/mL.[193] However, because the automated susceptibility systems are diagnostic devices regulated by the FDA, susceptibility test system manufacturers must perform a complex validation process before breakpoints can be changed on their systems, assuming that they even have dilutions appropriate for the new breakpoints.

In addition to microdilution methods, used by approximately 80% of laboratories in the US, disk diffusion susceptibility is used by approximately 15% of laboratories.[192] Antimicrobial-containing disks are applied to a lawn of bacteria inoculated on a standard medium, and after 16 to 24 hours of incubation, zones of inhibition are measured (Fig. 290.1A). Zones of inhibition correlate reasonably well with specific MIC values. Breakpoints for susceptible, intermediate, or resistant have been previously determined for each antibiotic disk based on zone size. Disk diffusion consistently is more accurate than automated commercial systems compared with reference methods,[192] is more flexible for choosing drugs for testing, and may better detect emerging resistance problems.[192] Disadvantages of disk diffusion testing are its labor intensiveness, lower reproducibility because of manual measurement of inhibition zones, lack of breakpoints for all clinically relevant bacteria, and proneness to clerical errors because of manual entry of results into clinical information systems.

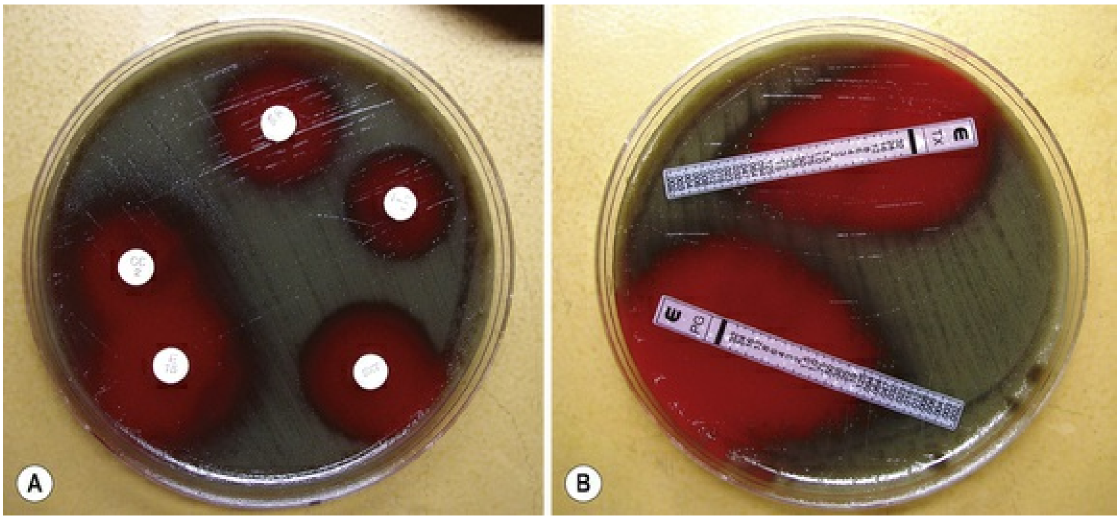

FIGURE 290.1 **Routine susceptibility testing of *Streptococcus pneumoniae.* (A) Kirby-Bauer disk diffusion. Disks, counterclockwise from top: vancomycin, levofloxacin, trimethoprim-sulfamethoxazole, erythromycin, and clindamycin. (B) Minimal inhibitory concentration (MIC) determination by Etest (bioMérieux, Durham NC). This isolate was susceptible to all antimicrobial agents tested, with ceftriaxone**

(TX) and penicillin (PG) MICs of 0.064 μg/mL.

Etest (bioMérieux) is performed in a manner similar to disk diffusion, but instead of a disk being placed on a lawn of bacteria, a plastic strip impregnated with a gradient of a specific antimicrobial agent is tested.[194] After appropriate incubation, the MIC is read where the elliptical zone of inhibition of growth meets the strip (Fig. 290.1B). Although not as highly standardized as disk diffusion, Etests are particularly useful and accurate compared with reference MIC methods for determining antimicrobial susceptibility for organisms that are fastidious or do not have disk diffusion breakpoints[195] (see Fig. 290.1B). Some agent-organism combinations do not have good correlation between Etest and broth microdilution. Two prominent examples are vancomycin and ceftriaxone for *S. aureus,* in which Etest MICs are significantly higher than MICs determined by broth microdilution.[196,197]

Screening for High-Level Aminoglycoside Resistance

All enterococci demonstrate low-level resistance to aminoglycosides but can acquire high-level resistance primarily through production of aminoglycoside-modifying enzymes.[44] Unlike strains with low-level intrinsic resistance, strains with high-level aminoglycoside resistance do not show synergistic inhibition with cell wall–active agents.[44] Standard susceptibility testing cannot differentiate intrinsic low-level resistance from acquired high-level resistance. Disks containing high concentrations of gentamicin (500 μg/mL) and streptomycin (2000 μg/mL) are highly accurate in detecting high-level resistance compared with reference MIC methods. High-level gentamicin resistance of *Enterococcus* also predicts high-level resistance to tobramycin and amikacin.

Molecular Methods

Molecular methods have been replacing traditional methods in the clinical microbiology laboratory, particularly when a specific pathogen or resistance gene is sought. The molecular detection of clinically relevant resistance can be accomplished using probe hybridization, nucleic acid amplification tests (NAATs) such as PCR, and DNA sequencing.

Probe detection occurs by hybridization, or annealing, of a labeled probe to a target sequence. The target sequence is released from organisms during lysis, which is followed by hybridization in either a liquid or solid phase. The probe acts to capture the target sequence of interest from a milieu of sequences. The use of solid-phase hybridization on nitrocellulose (i.e., line probe assays) allows for the detection of multiple sequences or polymorphisms from a single preparation. The most commonly used NAAT is real-time PCR (rt-PCR), which uses sequence-specific primers and probes to detect genes of interest. Incorporation of the probe detection in the same reaction vessel as the amplification process allows for less contamination, faster turnaround time, and greater sensitivity and specificity compared with traditional NAAT detection platforms. Probes can be designed to allow for the detection of resistance related to acquired genes, as well as intrinsic gene polymorphisms.[198]

DNA sequencing can be used to detect resistance mechanisms that rely on intrinsic gene mutations and demonstrate a strict genotype-phenotype correlation. Sequencing and subsequent mutation analysis have long been applied to the detection of antiviral resistance in HIV and, more recently, cytomegalovirus. The use of sequencing for the detection of antimicrobial resistance in bacteria is confined largely to research and public health applications. Sequence-based resistance detection in *M. tuberculosis*, for example, detects mutations for rifampin and INH resistance with 97% and 91% sensitivity, respectively, and for ethambutol, pyrazinamide, fluoroquinolone, kanamycin, capreomycin, and amikacin resistance with varying sensitivities.[170]

The interpretation of molecular detection of antimicrobial resistance results can be complicated when (1) the resistance mechanism is multifactorial, (2) the genotype-phenotype resistance relationship is clinically uncertain, (3) the infection is polyclonal,; or (4) synergy exists among multiple resistance phenotypes. Use of molecular resistance detection should be limited to organisms and infections in which the results can be interpreted with confidence for clinical treatment or infection control practices.

Special Considerations

Detection of Extended-Spectrum β-Lactamases

The increasing presence of ESBLs in Enterobacteriaceae has led to changes in the detection of resistance to cephems. In 2010, the CLSI lowered cephalosporin breakpoints.[193] Implementation of these lower breakpoints precludes the need for confirmatory testing because ESBL-producing organisms are interpreted as resistant. This also allows for individual drugs to be reported as tested, as opposed to modifying susceptibility reports based on the results of a phenotypic ESBL test. However, some automated susceptibility testing systems cannot accommodate these lower breakpoints because the concentration of drug tested is not low enough for some of the cephalosporins. Confirmatory testing is warranted if the revised breakpoints cannot be implemented.

Both phenotypic and molecular methods can be used to detect ESBLs.[54,120,191] A widely used, highly accurate phenotypic method employs combination disks containing clavulanic acid with either ceftazidime or cefotaxime, versus the cephalosporins alone. If the zone size of inhibition around the combination disk is ≥5 mm around the cephalosporin alone, the isolate is considered to be ESBL producing (Fig. 290.2).[54,191] Other phenotypic approaches include Etest and MIC tests that detect threefold or greater lowering by clavulanic acid of MIC of the extended-spectrum cephalosporin. Most automated susceptibility testing systems also include a screen for ESBL production, with acceptable sensitivity and specificity. Chromogenic agars can identify possible ESBL-producing isolates for further confirmation, with reported sensitivities of 95% to 97% and specificities of 94% to 95%.[199,200] Molecular methods for the detection of ESBLs are often limited to select targets, but they have been shown to be accurate when included in broad multiplex assays including those used to detect resistance directly from positive blood cultures.[201–203]

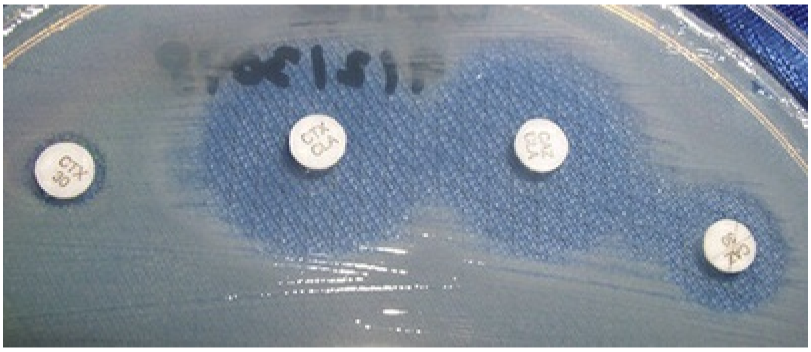

FIGURE 290.2 **Disk diffusion testing for extended spectrum β-lactamase (ESBL) production in *Klebsiella.* Disks, from left to right: CTX (cefotaxime), CTX CLA (cefotaxime and clavulanic acid), CAZ CLA (ceftazidime and clavulanic acid), and CAZ (ceftazidime). Inhibition zones are measured, and an increase of 5 mm in the clavulanic acid–containing disk relative to the corresponding cephalosporin alone indicates production of an ESBL. This isolate produces an ESBL.**

Detection of Carbapenem Resistance

Carbapenemase production in Enterobacteriaceae is signaled by decreased susceptibility, although not necessarily resistance, to carbapenems (e.g., MIC ≥2 μg/mL). The CLSI lowered carbapenem breakpoints to detect carbapenem resistance more accurately without the need for confirmatory tests. If these lowered breakpoints have not been adopted, laboratories should screen Enterobacteriaceae with an MIC ≥2 μg/mL of ertapenem, imipenem, or meropenem for carbepenemase production. Testing then can be performed using either the modified Hodge test[191,204] or the Carba NP (Carbapenemase Nordmann-Poirel) test.[205,206] If 2017 CLSI susceptibility breakpoint of ≤1 μg/mL is adopted, further testing of susceptible isolates need not be performed (see Table 286.7 and text). In the modified Hodge test, ertapenem and meropenem disks are placed on a lawn of a susceptible control strain of *E. coli*. A loopful of test organism (an isolate with increased carbapenem MIC) is inoculated in a straight line out from the edge of the disk (Fig. 290.3). After incubation, enhanced growth of the control *E. coli* strain at the intersection of the test streak and the carbapenem zone of inhibition indicates carbapenemase production by the test organism. In the Carba NP test, the organism is inoculated into a phenol red based buffer with or without imipenem. Hydrolysis of the imipenem by the organism leads to a color change from red to orange or yellow. When carbapenemase is detected, resistance is reported for all carbapenems regardless of MICs. Chromogenic agars have been developed for the detection of carbapenem-resistant Enterobacteriaceae. Compared with PCR, sensitivity and specificity of CHROMagar (Becton Dickinson, Franklin Lakes, NJ) KPC were 100% and 98%, respectively,[207] and positive and negative predictive values were calculated as 100% and 99%, respectively.[208] Chromogenic agars may be most beneficial for rectal surveillance cultures, but they can require broth enrichment for optimal sensitivity.[209]

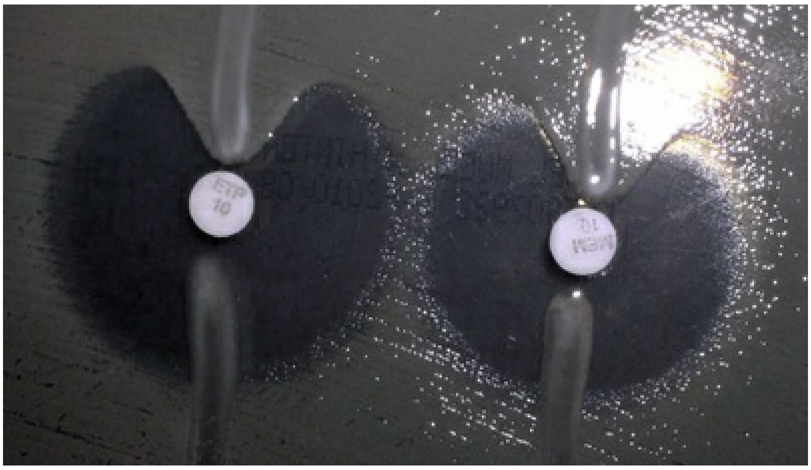

FIGURE 290.3 **Modified Hodge test for the detection of carbapenemase-producing Enterobacteriaceae. A lawn of *Escherichia coli* ATCC 25922 is spread on Mueller-Hinton agar, and 2 disks (10 μg ertapenem [ETP] and 10 μg meropenem [MEM]) are placed in the center of the agar a minimum of 30 mm apart. Test organisms are struck away from the disk, with each streak being a minimum of 25 mm. The test organism struck at the top permits growth enhancement of the sensitive *E. coli* strain; this indicates production of carbapenemase. No growth enhancement is seen with the test organism struck at the bottom, thus indicating no production of carbapenemase.**

Detection of Methicillin and Oxacillin Resistance

Several approaches can be used to detect β-lactam resistance resulting from altered PBPs in *S. aureus.* The gold standard for detection is PCR to detect the *mecA* gene or latex agglutination to detect its gene product, PBP2a. For routine susceptibility testing, cefoxitin disk testing is preferred over oxacillin disk testing because the clarity of cefoxitin zone of inhibition is superior.[210] Agar that contains 6 μg/mL of oxacillin supplemented with 4% sodium chloride also can be used for oxacillin resistance screening. All phenotypic methods compare favorably with molecular techniques.[211]

Both molecular and screening culture techniques have been developed for the detection of MRSA carriage. Several commercially available selective and differential chromogenic agars offer MRSA-positive results in 24 to 48 hours directly from clinical specimens and have performance characteristics similar to those of PCR.[212] Reportedly, broth enrichment before chromogenic agar culture improves the sensitivity of culture,[213] but it also increases the time to result. Because MRSA colonization often is associated with low bacterial counts, broth enrichment and molecular methods can provide optimal sensitivity.[213]

Conventional and rt-PCR can detect *mecA* in bacterial isolates and directly on patients' specimens. However, direct specimen testing has limitations, often including a lower positive predictive value than that of culture-based assays.[214–217] The emergence of *mecC*-mediated resistance may require new strategies for detection of MRSA. Additionally, several commercial assays are available for the detection of MRSA directly from positive blood cultures. These assays vary widely in terms of time to result, as well as the inclusion of nonstaphylococcal targets, but have widespread use in the clinical laboratory.

Detection of Vancomycin Resistance

Molecular and phenotypic methods are available to detect vancomycin resistance in *Enterococcus* spp. and *S. aureus*. Routine susceptibility testing and isolate screening using brain-heart infusion agar containing 6 μg/mL of vancomycin will detect vancomycin resistance in *S. aureus* and *Enterococcus* spp.[191] However, the brain-heart infusion agar screening plate does not reliably detect VISA strains.[191] Etest and microbroth dilution MICs can be used for detection of VISA and VRSA, but disk diffusion should not be used because it cannot differentiate high-level from low-level resistance accurately and can miss VISA.[112,191]

FDA-cleared assays are available for the detection of VRE rectal colonization for infection control purposes and for the detection of

VRE from positive blood cultures. Two main advantages of molecular detection of VRE rectal colonization are as follows: (1) amplification technology reportedly increases VRE detection to up to 120% and thereby permits better infection control; and (2) intrinsically resistant enterococci are excluded, thus mitigating unnecessary contact precautions and cost.[198] Detection of VRE from positive blood culture bottles allows for earlier detection and therefore appropriate treatment.[218] A current list of FDA-cleared assays can be found on the FDA website (http://www.fda.gov/MedicalDevices/ProductsandMedicalProcedur The assays available for rectal screening detect either *vanR* or *vanA*. Because these genes rarely are found in nonenterococcal species, many assays do not incorporate an *Enterococcus*-specific target. The assays used for the detection of VRE from positive blood cultures include enterococcal-specific targets to provide species-level identification as well as detection of *vanA*.

Detection of Inducible Clindamycin Resistance

MLS_B-I organisms test as resistant to erythromycin, but they appear to be susceptible to clindamycin by routine disk diffusion and MIC testing. The D-test detects inducible resistance to clindamycin in the presence of erythromycin. Erythromycin and clindamycin disks are placed within close proximity (15–26 mm for staphylococci and 12 mm for streptococci) on agar seeded with the clinical isolate.[191] If inducible resistance is present, the clindamycin inhibition zone closest to erythromycin will flatten, resembling a “D” (Fig. 290.4). Some automated susceptibility testing systems screen for inducible clindamycin resistance by comparing the susceptibility results from a well containing clindamycin alone with a well containing both clindamycin and erythromycin. The Vitek 2 inducible resistance screen has lower sensitivity (80%–93%) than the D-test.[219,220] The CLSI recommends that laboratories screen for inducible clindamycin resistance on all β-hemolytic streptococci and staphylococci.[191] Although the clinical relevance of the detection of inducible resistance in the setting of a patient not receiving erythromycin is debatable in theory, in practice several reports have noted failed clindamycin therapy for infection with an MLS_B-I organism.[126]

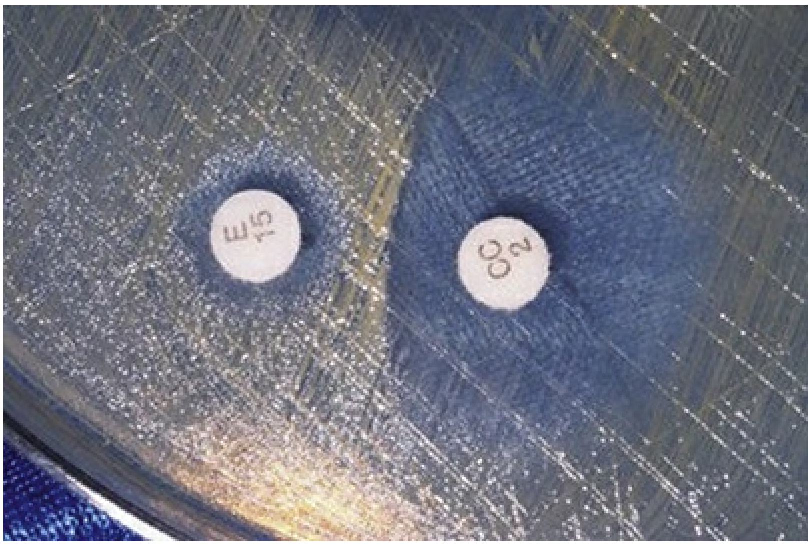

FIGURE 290.4 **D-test for the detection of inducible clindamycin resistance in *Staphylococcus aureus.* The CC 2 disk on the right contains 2 µg of clindamycin; the E 15 disk on the left contains 15 µg of erythromycin. Disks are placed 15 to 26 mm apart, and a flattening of the clindamycin zone proximal to the erythromycin disk is observed, indicating inducible resistance to clindamycin.**

Detection of Isoniazid and Rifampin Resistance in *Mycobacterium tuberculosis*

Molecular detection of resistance in *M. tuberculosis* is particularly attractive because of the organism's slow growth rate and the emergence of MDR *M. tuberculosis* (resistant to both rifampin and INH with or without resistance to other first-line drugs) and extensively drug resistant *M. tuberculosis* (MDR *M. tuberculosis* that is also resistant to fluoroquinolones and 1 of the injectable agents, capreomycin, amikacin, or kanamycin). The reference method, agar proportion testing, is slow and labor intensive. In most clinical laboratories, agar proportion testing has been superseded by automated broth susceptibility testing, which is faster, more convenient, and has similar accuracy.[221] Although faster, automated broth methods still require days to weeks to complete.

The World Health Organization recommends that the Xpert MTB/RIF test (Cepheid, Sunnyvale, Calif) be used globally in the fight to reduce the spread of MDR and extensively drug-resistant tuberculosis (http://www.who.int/tb/laboratory/xpert_launchupdate/en/). Using an automated system, Xpert MTB/RIF can detect *M. tuberculosis* complex DNA and screen for rifampin resistance directly from pulmonary specimens in <2 hours.[222] Five probes that hybridize to the RRDR region of *rpoB* are used to detect rifampin resistance. If at least 1 probe does not produce a signal (indicating a mutation at the hybridization site) or if ≥3.5 cycle difference exists between probe signals (indicating less efficient hybridization as a result of mutation), then a positive result for rifampin resistance is reported. Compared with traditional susceptibility testing, Xpert showed 97.6% sensitivity and 98.1% specificity; however, this study took place in countries with a higher prevalence of tuberculosis and MDR tuberculosis than the US (Peru, Azerbaijan, South Africa, and India).[222] In the US and other areas of low prevalence, the positive predictive value is likely to be lower. A positive rifampin resistance result by Xpert will be obtained even for synonymous (i.e., silent) mutations[223]; therefore, it is critical that molecular rifampin resistance results be confirmed by traditional susceptibility testing. Molecular confirmation of results can also be obtained through the Molecular Detection of Drug Resistance (MDDR) service of the Centers for Disease Control and Prevention (CDC) (http://www.cdc.gov/tb/topic/laboratory/guide.htm). The CDC has published recommendations for interpretation of rifampin resistance molecular results obtained by the Xpert MTB/RIF test.[224]

Two commercially available assays that are CE–marked for clinical use in Europe use a combination of NAAT and a probe-based line blot for the detection of resistance in *M. tuberculosis.* The INNO-LiPA Rif.TB kit (Fujirebio, Ghent, Belgium) detects rifampin resistance using a combination of 5 sensitive probes and 4 resistant probes detecting *rpoB* mutations.[225] The Genotype MTBDRplus assay (Hain Lifescience, Nehren, Germany) detects both rifampin and INH resistance by detecting mutations in *rpoB*, *katG*, and i*nhA*. Sensitivity is greater for the detection of rifampin (>95%) than for INH resistance (~85%), likely because of the wider array of mutations that can confer resistance in INH.[226] Additional line probe assays (Genotype MTBDRsl, Hain Lifescience) have been developed for the detection of resistance to ethambutol and second-line drugs. Performance of this test appears to be reasonably good for the detection of fluoroquinolone, aminoglycoside, and capreomycin resistance (sensitivity and specificity between 75% and 100%) but less sensitive (~60%) for detecting ethambutol resistance.[227,228] Agar proportion susceptibility testing is still the gold standard because of incomplete data on all mutations or target genes associated with phenotypic resistance. However, if molecular detection is used as an initial screening assay, resistant isolates can be detected weeks earlier, with significant impact on clinical care.

Susceptibility Testing of *Pseudomonas aeruginosa* Isolates From Patients With Cystic Fibrosis

Susceptibility testing of *P. aeruginosa* from chronically infected patients with cystic fibrosis presents a special challenge because of the unique nature of strains, multidrug resistance, a unique mucoid phenotype, and possible growth under anaerobic conditions distal to mucus plugs.[229] Automated systems have inferior accuracy in assessing antimicrobial resistance of mucoid *P. aeruginosa*. Because of the comparatively slow growth of these mucoid organisms, major errors can occur with automated susceptibility testing systems in which the organism is reported as susceptible when in fact it is resistant to a drug by reference methods. Both Etest and disk diffusion methods compare more favorably with reference methods.[229]

Reference MIC and disk diffusion methods can determine accurately *P. aeruginosa* resistance to several or all classes of antimicrobial agents, with the possible exception of colistin. Agar-based methods for detection of colistin resistance may not be reliable because this large, highly charged molecule diffuses poorly in an agar matrix and can adhere to plastic surfaces, thereby affecting broth test determinations. The use of a surfactant may mitigate this effect, but the overall impact of surfactant use needs to be studied further.[230,231] Additionally, standard tobramycin breakpoints, which are based on achievable serum concentrations of drug, classify as resistant isolates that in fact have MICs lower than achievable by aerosolized tobramycin (lower airway level ≥100 μg/mL). MIC determination or Etest can be used to determine higher relevant MICs. In 1 study, 20% of isolates with MICs suggesting intermediate susceptibility or resistance at the serum-achievable level would be susceptible at the aerosol-achievable level; 5% of isolates were resistant to tobramycin at aerosol-achievable levels.[232]

Other alternative strategies for *P. aeruginosa* susceptibility testing include checkerboard synergy testing and testing for multiple combined bactericidal activity.[233] In a randomized trial, the clinical outcome for patients whose therapy was based on multiple-combination bactericidal antibiotic testing was no better than for patients whose therapy was based on standard susceptibility methods.[234]

Finally, the mode of growth used in susceptibility testing of *P. aeruginosa* has been studied.[235] When *P. aeruginosa* is grown adherent to biofilms (sessile bacteria), β-lactam antibiotics are much less active than against organisms growing as single cells (planktonically). Aminoglycosides and ciprofloxacin showed similar activity against organisms growing planktonically or in biofilms. Surprisingly, macrolides, usually not thought to be active against *P. aeruginosa,* have activity against biofilm-grown organisms but not planktonic organisms.[235] Susceptibility testing of biofilm-grown organisms is complex, and questions of clinical utility are unsettled.[234]

Pharmacokinetic-Pharmacodynamic Basis of Optimal Antibiotic Therapy

Michael N. Neely, Michael D. Reed

As clinicians continuously strive to practice evidence-based medicine, the use of antibiotics can be frustratingly empiric. Ethical concerns, multiple confounding variables, and unclear end points hamper clinical infectious disease research. This empiricism is clearly evident in most recommendations for antibiotic dosing and duration of therapy, especially in children, because only a fraction of published pharmacokinetic (PK) and pharmacodynamic (PD) data is collected from this group of patients. Although pediatric data are more plentiful and better defined for antibiotics than for other drug classes used in pediatric patients, much more work needs to be done. The lack of specific and sound dosing and safety data for drugs used in children continues to hamper the ability to determine optimal dose regimens rapidly. “Off-label” use of medications in children unfortunately, and necessarily, remains common practice.[1–3] Moreover, suboptimal antibiotic dose regimens most certainly contribute to the continued emergence of the virulent, multidrug resistant bacteria we encounter at the bedside today.[4]

In response to this lack of pediatric data, the US Food and Drug Administration (FDA) was granted additional authority through the Best Pharmaceuticals for Children Act (BPCA, 2002, 2007, 2012) and the Pediatric Research Equity Act (PREA, 2003, 2007, 2012). The BPCA extends patent exclusivity for 6 months for subsequent research focused toward a pediatric indication for on-patent drugs and prioritizes and supports pediatric labeling studies with off-patent drugs. The PREA mandates that any drug with potential use in children must also be studied in children unless it is granted a specific waiver by the FDA. This act is enforced automatically with any new drug application, including new indications for existing drugs. Failure to comply with PREA requirements can result in revocation of marketing approval for a drug. Both the BPCA and the PREA were made permanent in 2012 as part of the FDA Safety and Innovation Act (FDASIA). With a growing awareness of the important physiologic differences across the age spectrum in children and their many important influences on drug dosing, knowledge of an antibiotic's PK and PD properties is necessary to determine optimal dosing. The increasing incidence of serious infections caused by multidrug-resistant pathogens combined with the ever-increasing emergence of virulent pathogen resistance underscores the importance of applying integrated antibiotic PK-PD–defined dosing in daily practice.[5,6] This chapter reviews basic PK principles and provides a framework for the clinician to apply these principles at the bedside.

Basic Concepts in Clinical Pharmacokinetics

Pharmacokinetics (PK) describes the time course of drug movement in the body; an understanding of a drug's PK profile is essential to the design of an optimal dosage regimen. However, focusing on a drug's PK profile alone provides the clinician with limited information about optimal drug dosing or, more importantly, clinical efficacy. PK principles are of clinical relevance only when they are integrated with the drug's *pharmacodynamic* (PD) properties (i.e., the effects of the drug in the patient).

With the exception of intravenous (IV) drug administration, a drug must be absorbed into the systemic circulation from its site of administration. Some drugs can be administered as a prodrug requiring in vivo metabolism to liberate the active moiety. Once absorbed, the drug is distributed within the body to accessible sites that are specific to the individual drug or drug class based on inherent physicochemical characteristics (e.g., lipid solubility, molecular weight, protein binding). Factors such as age, body habitus, and disease can influence this distribution. Simultaneous with the processes of absorption and distribution, many drugs undergo metabolism before excretion from the body. A drug's PK and disposition profile can be artificially separated into semidiscrete periods of drug absorption, distribution, metabolism, and excretion (Fig. 291.1), to permit visualization and more accurate quantification. Knowledge of this information allows the clinician to predict drug concentrations and systemic exposures for the active drug that can be achieved at any time over a specified dosing interval after any dose of a given drug. With this information, an optimal drug dose and dose interval can be determined for any patient with a regimen that accounts for underlying pathophysiologic features and major organ function.

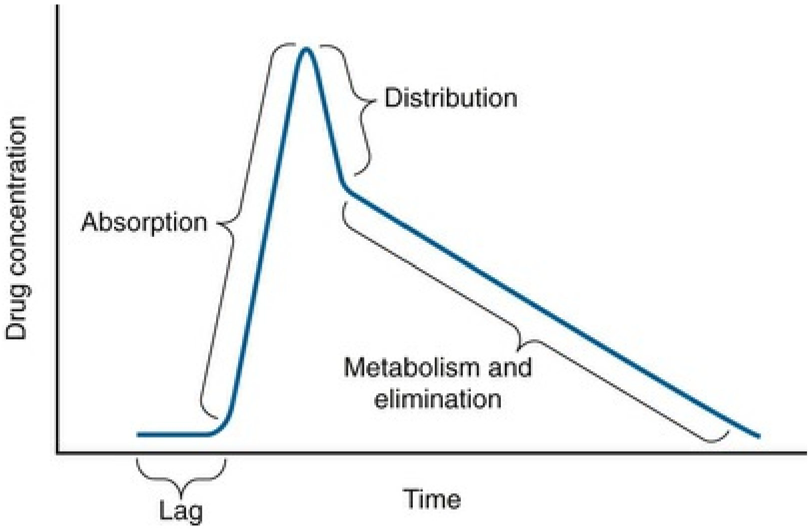

FIGURE 291.1 **Overall biologic fluid (e.g., serum) drug concentration–time curve after extravascular drug administration. Each important process of drug disposition is indicated. Although these processes are compartmentalized graphically in the figure, in reality they occur simultaneously (see text for details).**

The PK property *bioavailability* estimates the amount of a drug dose administered extravascularly (e.g., orally, intramuscularly) that is absorbed into the systemic circulation. Bioavailability is calculated as the area under the plasma drug concentration–time curve (AUC) achieved after extravascular drug administration divided by the AUC achieved after IV administration (e.g., AUC_{oral} / AUC_{IV}). Thus, to achieve the same systemic exposure with a drug administered orally as achieved with IV dosing, one simply divides the IV dose by the drug's bioavailability (obtained from published sources) to determine the equivalent oral dose. Lower bioavailability is not necessarily a negative attribute unless the dose required is so large that the patient tolerates it poorly. However, for orally administered antibiotics, poor bioavailability can be a major limitation because unabsorbed drug remaining in the intestinal tract can adversely affect indigenous flora and often can lead to intestinal complaints and diarrhea (e.g., ampicillin vs. amoxicillin). Conversely, this property is sometimes therapeutically advantageous, as is the case for orally administered vancomycin to treat *Clostridium difficile*–associated colitis or nystatin for mucosal candidiasis.

Bioavailability depends on the molecular weight, solubility, and permeability of the drug. Highly soluble and permeable drugs have excellent bioavailability, whereas the converse results in poor bioavailability. Drugs with opposing solubility and permeability have unpredictable and variable bioavailability, even within the same patient from dose to dose, because of variations in gastrointestinal pH, motility, and food content. Drugs can exhibit complex absorption patterns with delayed or multiple peaks in their blood (plasma or serum) concentrations arising from timed-release formulations, enterohepatic recycling, site-specific absorption within the gastrointestinal tract, or variations in gastric emptying and intestinal transit times. A drug's *peak plasma concentration* is the characteristic most greatly affected by changes in the rate and extent of absorption, and reduced peaks theoretically can compromise the efficacy of concentration-dependent antibiotics, as discussed in the later section on pharmacodynamic correlates for antibacterial agents.

Once absorbed into the systemic circulation, the distribution of a drug depends on specific characteristics inherent to the drug molecule. Small, non–protein-bound, nonionized lipid-soluble molecules are usually widely distributed (e.g., azithromycin), whereas larger, less lipid-soluble (i.e., polar) or highly protein-bound drugs traverse cell membranes poorly, thus restricting movement (e.g., aminoglycosides, vancomycin, echinocandins). The PK measurement that attempts to describe this process is the *volume of distribution* (V_d). V_d is a proportionality constant that relates the amount of drug in the body to its plasma concentration. V_d can be roughly conceptualized for an IV drug by the following simplified formula: V_d = dose / C_p, where C_p is the peak plasma drug concentration. V_d does not correspond to any true anatomic distribution or compartment, although the magnitude of V_d provides clues about a drug's physiologic distribution. For example, for a drug with a very small V_d (i.e., 0.2 L/kg), a larger proportion of the drug is confined to extracellular fluid (composed of intravascular and interstitial fluid), whereas the distribution of a drug with a large V_d can involve extensive tissue binding, intracellular distribution, or both. Knowing a drug's V_d (expressed in liters per kilogram of body weight) allows the clinician to estimate the dose necessary to achieve any desired plasma drug concentration. For example, the loading dose for a drug can be calculated from the following formula: loading dose = desired plasma drug concentration (mg/L) × V_d (L/kg) × patient body weight (kg). The age-specific V_d for the drug to be prescribed can be obtained from published sources or calculated for the individual patient, as outlined earlier. As inferred from the loading dose calculation, the first (or loading) dose of any drug is independent of a patient's organ function or extent of underlying disease (e.g., renal failure). A patient's first drug dose is dependent only on the V_d of the specific drug; all subsequent doses depend on the patient's ability to clear (eliminate or metabolize) the drug.

The PK property *clearance* (CL) estimates the volume of solvent (e.g., plasma, serum, or blood) from which all drug is removed per unit time. CL is therefore expressed in units of volume per time. *Body CL* is a composite estimate reflecting all mechanisms of drug CL, including renal, hepatic, and other forms of CL (e.g., lung), and it is calculated using the following formulas: CL = 0.693 × V_d / $t_{1/2}$, where $t_{1/2}$ is the *drug's elimination half-life;* or CL = drug dose × F /

AUC, where F is bioavailability. Knowledge of a drug's CL is necessary to determine accurately the need for and proper timing of subsequent doses to maintain any desired drug concentration or degree of systemic exposure. Changes in organ function responsible for drug removal from the body are reflected by changes in a drug's overall CL rate. Although clinically the $t_{1/2}$ often is used at the bedside as a measure of drug CL and to determine subsequent drug dosing, this value merely reflects the time required for a given drug concentration in any biologic fluid to decrease by 50%, although this is not necessarily elimination from the body, as exemplified by all forms of amphotericin. If V_d is fairly constant in a patient in stable condition, $t_{1/2}$ mirrors body CL, thereby permitting bedside application. The $t_{1/2}$ can be estimated simply from the measured fall in plasma drug concentration after an individual dose (e.g., from the peak and trough plasma drug concentrations); to estimate the $t_{1/2}$ in practice, usually one must obtain 2 measured drug concentrations and calculate $t_{1/2}$ as $\ln(2) \times -t / \ln(C2/C1)$, where ln(2) is the natural logarithm of 2 (~0.693) and t is the time between the 2 measured concentrations C1 and C2. Although the $t_{1/2}$ is an extremely useful bedside application of PK, the accuracy of the $t_{1/2}$ as a reflection of drug CL diminishes in situations of changing V_d, renal or liver function. For example, a drug's V_d can be altered during extracorporeal membrane oxygenation (ECMO), septic shock, or severe liver disease with marked ascites.

The PK principles just outlined for V_d, CL, and $t_{1/2}$ assume that the drug follows *first-order* or *linear PK characteristics. First order* means that a constant *fraction* of drug is cleared per unit time (i.e., regardless of the initial concentration, the time to clear x% is the same). However, for certain drugs, such as voriconazole[7,8] and phenytoin,[9] the CL mechanisms can be saturated at clinically relevant concentrations, and thus their disposition is best described by using *zero-order methodology* or a combination of first-order elimination at lower concentrations and a gradual transition to zero-order elimination at higher concentrations (i.e. *Michaelis-Menten* kinetics). *Zero order* means that a constant *amount* of drug is cleared per unit time (i.e., the higher the initial concentration, the longer it will take to clear x%). Fortunately, most drugs used clinically follow first-order PK, which is simpler to apply clinically. The recognition that a drug's disposition characteristics are first order allows the clinician to use simple proportions with relative accuracy to define patient-specific drug doses. For example, if a patient's steady-state plasma drug concentration is half that desired (at any time point) and the drug follows first-order PK, the dose can simply be doubled to achieve the desired concentration. In contrast, for a drug with zero-order characteristics, doubling the dose can result in a much higher increase in the plasma concentration.

Following repeated drug dosing, a *steady-state* condition is achieved (i.e., when the amount of drug administered to the patient equals the amount of drug eliminated [cleared] from the body). Simply put, "in = out." The importance of steady-state conditions cannot be overemphasized because the drug concentrations in blood (plasma or serum) or tissue reported to be associated with drug efficacy or toxicity most often are the steady-state drug concentration. For drugs that follow first-order "proportional" PK characteristics, the drug's $t_{1/2}$ can be used to estimate the time to reach steady state (i.e., 4–5 times the $t_{1/2}$ to reach steady state). A drug's $t_{1/2}$ can be calculated for an individual patient as described earlier, or an age-appropriate $t_{1/2}$ often can be obtained from published sources and modified if necessary based on the patient's elimination organ function.

Unfortunately, the clinician encounters many patients who deviate from the proposed PK characteristics found in published sources, especially in pediatrics. A far more sophisticated, powerful, and nuanced approach to dosage individualization is the application of population PK modeling techniques coupled with bayesian feedback, by using specifically designed software tools.[10,11] Although these methods have the disadvantage of requiring specialized software, training, and knowledge, they have numerous advantages, including more accurate and rapid attainment of target drug concentrations without the need for steady-state conditions (including patients with unstable PK behavior),[12–15] improved clinical outcomes,[16–20] and reduced costs.[16,21–24] A complete review of this topic is beyond the scope of this chapter, but interested readers are urged to contact experts in the field and consider these approaches when desiring to optimize individual therapy.

The next sections discuss the general PK alterations that can influence both the magnitude and the frequency of antibiotic doses in neonates, patients with organ failure who are undergoing dialysis or ECMO, children with cystic fibrosis (CF), and patients with burns or septic shock. However, considerable variability exists within these generalizations, and any specific patient is likely to be best served by careful dose optimization in partnership with an expert in clinical pharmacology.

Drug Disposition in Specific Patient Populations

Neonates: the Ontogenic Basis of Drug Disposition

As children mature physically, they also mature physiologically. This principle has important and clinically relevant implications for both drug PK and PD characteristics.[25,26] Factors that influence drug absorption from the gastrointestinal (GI) tract include the surface area available for absorption, pH, gastric emptying time, exocrine pancreatic function, size of the bile acid pool, and bacterial colonization (Table 291.1). All these functions are variably altered in neonates, particularly those born prematurely, and in young infants relative to older children and adults.[27,28] Changes in the amount and distribution of body water in neonates, as well as differences in quantitative and qualitative protein-binding characteristics, also are present and affect drug distribution. These ontogenic differences in body water composition (i.e., increased V_d for water-soluble drugs) are reflected by the increased individual doses, on a milligram of drug per kilogram of body weight basis, prescribed for young infants and children compared with older children and adults. Although far from fully characterized, both the oxidative and conjugative hepatic metabolic enzyme systems are immature at birth and reach adult levels of activity at various times throughout early childhood.[29] Renal function and elimination also mature as a function of gestational and postnatal age, with glomerular filtration reaching adult levels in infants of 34 weeks of gestation by approximately 3 to 5 months of age.[30] Tubular secretion matures more slowly and reaches adult levels by approximately 8 to 9 months of age (see Table 291.1).

TABLE 291.1

Physiologic Changes in Children That Affect the Pharmacokinetic Characteristics of Drugs

Parameter	Neonates	Approximate Age Approaching Adult Level
ABSORPTION		
Gastric pH	↑	3 mo
Gastric emptying	↓	6–8 mo
Pancreatic function	↓	9 mo
DISTRIBUTION		
Body water	↑[a]	~3 yr
Protein binding	↓	12 mo
METABOLISM		
Hepatic drug-metabolizing or hepatic drug metabolism	↓	2 yr to adolescence
ELIMINATION		
Renal function	↓	Glomerular filtration: 3–5 mo
		Tubular secretion: 8–9 mo

[a] The distribution of body water depends on age: the total body water (TBW) of neonates is approximately 75% of body weight, with approximately 50% intracellular (IC) and 50% extracellular (EC). A gradual decrease in TBW and a shift to IC distribution occur until adult values of 50% to 60% TBW, 33% EC, and 66% IC are reached at puberty.

Data from references 328 to 331.

As a result of these physiologic differences (see Table 291.1), infants <44 weeks of postconceptional or postmenstrual age generally have larger V_d and decreased antibiotic CL, which translate clinically to lower peaks, lower overall plasma drug concentrations, and longer $t_{1/2}$ than observed in older infants and children. Furthermore, these infants can be more susceptible to drug-drug interactions at all levels, interactions that are likely to be significant for other drugs as well as antibiotics alone (see the later section on the basis for drug-drug interactions).

The physiologic differences of young infants influence not only drug PK but also PD characteristics, which necessarily incorporate the mechanism of drug action. Developmental changes in receptor function are not as relevant to antibiotics because the receptor targets are on the infecting organism.[31] However, host receptors can be involved in therapeutic antibiotic mechanisms (e.g., human kinases that phosphorylate acyclovir) or adverse antibiotic mechanisms. Despite lower CL and prolonged $t_{1/2}$ in neonates relative to older children and adults, aminoglycosides cause less nephrotoxicity in neonates.[32] This tolerance is thought to arise from differences in renal disposition characteristics, although the exact mechanism is unknown.

The clinician must be aware that neonates are physiologically distinct and manifest altered antibiotic PK characteristics. Dosing strategies should be evaluated critically to make prescribing decisions to optimize therapeutic success. In the absence of neonatal dosing recommendations, knowledge of the altered PK patterns will make empiric dosing more rational when it is extrapolated from dosing recommendations for older children or adults.

Patients With Organ Failure and Principles of Dialyzable Drugs

The major routes of drug elimination are by the kidneys into urine and by the liver into bile. For most drugs only minor amounts are eliminated into other body fluids. Alterations in drug disposition result from failure of either of these organs of elimination or failure of the cardiopulmonary system to support their proper function. Patients in cardiopulmonary failure can experience alterations both in V_d as a result of increased total body water and in CL as a result of hepatic or renal dysfunction. Knowledge of the PK properties of individual drugs is crucial to understanding the magnitude of such effects. Drugs with a small V_d are more greatly affected because they tend to be distributed to extracellular fluid. The route of metabolism and elimination determines the impact of hepatic or renal dysfunction.

Extracorporeal Membrane Oxygenation

ECMO influences drug disposition in several ways. ECMO circuitry can add up to 500 mL of volume to the patient, in which case V_d is increased; children weighing <20 kg will most likely experience corresponding lower peak drug concentrations and a longer $t_{1/2}$. Further, drugs can bind to the oxygenation membrane, thereby potentially increasing both V_d and CL.[33] Binding is increased with increasingly lipophilic drugs. CL can be reduced as a consequence of altered perfusion of the liver and kidneys.[34,35]

Alterations in the PK characteristics of antibiotics during ECMO have been relatively well characterized for gentamicin and vancomycin.[36,37] Although the V_d of aminoglycosides is variably increased, the $t_{1/2}$ can be doubled. Neither drug significantly binds to the oxygenation membrane, as predicted by low lipophilicity. The implication for dosing is that aminoglycosides should be administered every 18 to 24 hours initially (or less frequently in patients with renal failure) to infants undergoing ECMO (with monitoring of serum drug concentrations), although no efficacy studies are available to support this recommendation. For vancomycin, V_d and $t_{1/2}$ are increased, and CL is decreased, resulting in a suggested initial dose of 20 mg/kg IV every 18 to 24 hours for infants with a serum creatinine value <1.5 mg/dL. For infants with a higher serum creatinine concentration, the dosing interval must be extended. In all cases, serum vancomycin concentrations should be monitored.

Increased ECMO-associated cefotaxime V_d has been documented, but the percentage of the dosing interval that is greater than the organism's minimal inhibitor concentration (MIC) after standard doses during ECMO is not significantly different from the same doses while the patient is not undergoing ECMO, thus leading to no required dosing changes.[38] Some reports have noted lowered plasma voriconazole concentrations requiring higher doses in patients receiving ECMO, a finding consistent with its high lipophilicity, and therapeutic drug monitoring is recommended.[39,40] Caspofungin, which is less lipophilic, had reportedly lowered[41] and unaltered[40] concentrations in 3 patients receiving ECMO, with the result that no clear recommendation was made. Oseltamivir PK does not appear to be changed significantly.[42] Indeed, a case report of a 6-year-old boy receiving both ECMO and continuous veno-venous hemofiltration demonstrated that low plasma levels of oseltamivir were likely caused by poor oral absorption rather than by marked changes in V_d or CL.[43]

For other antimicrobial agents for which plasma drug concentrations are unavailable, the clinician can only estimate dosing modifications based on the expected changes described earlier.[34,35] In general, V_d and $t_{1/2}$ are the same or are increased. Lipophilic drugs are more greatly affected than are hydrophilic drugs. However, patients undergoing ECMO usually have multiorgan failure, with renal failure and the use of continuous veno-venous hemofiltration the most problematic for many antibiotic regimens.

Dialysis

For patients in acute or chronic renal failure who require dialysis, several options can be used for extracorporeal therapy, including intermittent or continuous hemodialysis (HD), hemofiltration (HF), or peritoneal dialysis (PD). HD and HF therapies can be combined.[44,45] HD removes an antibiotic by diffusion across the dialysis membrane into the dialysate according to the drug's concentration gradient. The amount of blood flow past the dialysis membrane and the composition and flow of dialysate influence the amount of drug removed. HF (without HD) removes antibiotics in the ultrafiltrate, which is a hydrostatically generated flow of water containing the dissolved drug. No drug concentration gradient is present. PD, in general, removes most antibiotics minimally. The volume of PD fluid generally is small (0.05–0.2 L/kg) in comparison with the V_d of antibiotics (0.2–>100 L/kg), so only a very small percentage of the total drug in the body is distributed to the PD fluid unless the antibiotic has a similarly small V_d. Furthermore, the intraperitoneal concentration of antibiotics is proportional to the concentration of free, non–protein-bound drug. The protein content of typical dialysate fluid is 0, so highly protein-bound antibiotics are poorly distributed to the peritoneal fluid. Increasing the amount of PD dialysate or the frequency of exchange increases the amount of drug extracted, but a cumulative amount extracted of <25% during a dosing interval is usually insignificant. In contrast, antibiotics administered into the peritoneal dialysate can reach therapeutic plasma concentrations if they can cross the peritoneal membrane, passage through which is enhanced in the presence of inflammation. Because the potential extra-abdominal volume for an antibiotic to diffuse into is much larger than the intra-abdominal volume, with equal concentrations across the peritoneal membrane at equilibrium, the amount of drug in the body is greater than in the peritoneal dialysate.

All these modalities partially restore the ability of the body to eliminate an antibiotic that normally would be cleared by the kidneys. Although several thorough reviews have described the use of antimicrobial agents in these patients, none of the guidelines have pediatric dosing, and all strongly convey the same message: antimicrobial concentrations highly depend on factors intrinsic to the mode of dialysis itself and the drug's PK properties (Table 291.2). This variability could have significant clinical implications.[46,47] Although the clinician can apply principles outlined here to an individual patient to generate a qualitative assessment of the need for dose adjustment, confirmatory measurement of drug concentrations is crucial when possible.

TABLE 291.2

Factors That Increase the Likelihood of Antibiotic Removal by Dialysis

Factors Intrinsic to the Antibiotic	Factors Intrinsic to the Mode of Dialysis
Smaller volume of distribution (<1 L/kg)	CVVHDF[a] > CVVH[a] > CVVHD[a] > IHD ≫ PD
Smaller molecular mass (<2 kd)	Frequent dialysis
Reduced protein binding (<80%)	High flow rate of blood or dialysate
Neutral charge	Filter capacity and selectivity
Normally eliminated by kidneys (>30%)	Dialysate composition

[a] The differences in drug clearance among the continuous modes of hemodialysis or hemofiltration are less significant for small molecules, which include most hydrophilic antibiotics that are likely to be cleared by these modes. Among these, the largest are teicoplanin (1.9 kd), colistimethate, also known as colistin (1.8 kd), and vancomycin (1.5 kd).

CVVH, continuous venovenous hemofiltration; CVVHD, continuous venovenous hemodialysis; CVVHDF, continuous venovenous hemodiafiltration; IHD, intermittent hemodialysis; PD, peritoneal dialysis.

Drugs with a small V_d (<1.0 L/kg) that are primarily confined to the extracellular compartment are available for filtration across the dialysis membrane. The pore size of HD membranes is approximately 0.5 kd, whereas HF membranes are usually approximately 50 kd. Most antibiotics are <1 kd. Passage across a membrane is inversely proportional to the square root of the molecular mass. Drug-protein complexes are too large to pass through the pores of intact dialysis membranes, so highly protein-bound antibiotics (>80%) pass through the membrane poorly. Further, the membranes carry a net negative charge; highly polar molecules do not cross the membrane efficiently. Antibiotics that are mainly eliminated by a functioning kidney are more likely to be eliminated by dialysis, and a simplistic rule of thumb predicts some removal of drugs that are eliminated >30% unchanged in the urine in patients with normal renal function. However, the fraction of an antibiotic normally cleared by active tubular secretion is not compensated for by dialysis, and this factor should be considered in any patient manifesting unexplained signs or symptoms of drug toxicity.

Antibiotic dose adjustment in the absence of measurable drug concentrations in blood, dialysate, or ultrafiltrate, is a crude estimate, at best. Unfortunately, most pharmacology references consulted to determine dose recommendations use complicated formulas that require information the clinician often does not possess. Therefore a more intuitive approach is typical, and the clinician should first consider the relevance of potential drug accumulation by monitoring the patient closely for desired and undesired drug effects. Fortunately, most antibiotics have a very high therapeutic index (i.e., the ratio of therapeutic to toxic doses). “Safe” drugs can generally be allowed to accumulate moderately without risk of serious or irreversible toxicity, or both. In contrast, more rigorous dose adjustments should be applied for antibiotics that can be associated with toxicity (e.g., the aminoglycosides) because in general patients in renal failure, especially if they are uremic, are more prone to adverse effects from all drugs. Regardless of the dosing scheme selected, the clinician must monitor patients closely for specific evidence of toxicity related to the drug in question as well as expected clinical responses (see Chapter 289). Conversely, unaccounted-for extracorporeal elimination has major importance when subtherapeutic drug concentrations lead to clinical failure, which can happen when a drug dose is based on a patient's intrinsic renal function without accounting for dialysis-mediated drug CL. Therefore, for most antibiotics, it is more important to avoid underdosing. Appendix 291.1 lists suggested adjustments for selected antibiotics in response to renal failure with or without dialysis.

Cystic Fibrosis

CF is the most common potentially lethal genetic disorder in whites and remains a therapeutic challenge for pediatric and adult practitioners. The disease is characterized by an elevated sweat chloride concentration, pancreatic exocrine insufficiency, thick and tenacious mucus secretions, and chronic obstructive pulmonary disease.[48–50] A hallmark of CF is chronic microbial colonization of the lung with resultant repeated acute pulmonary infections or exacerbations.[48–51] CF morbidity and death result from the pulmonary component of this disease, and treatment (e.g., antibiotics, ibuprofen) focuses on decreasing the inflammation that is responsible for the progressive, irreversible deterioration in lung function[52] (see Chapter 106). However, optimal antibiotic therapy in patients with CF is complicated by potential differences in the disposition of many drugs.[53] Unfortunately, the lack of adequate control groups in many studies precludes definitive conclusions regarding CF-induced alterations in drug PK. Nevertheless, these data provide consensus findings that patients with CF often have a larger V_d and enhanced body CL for many antibiotics, including aminoglycoside and β-lactam agents, compared with patients who do not have CF,.[53–55] The reasons for these differences are unknown. CF-induced differences in drug V_d may merely reflect the difference in body composition in patients with CF, specifically, their limited adipose tissue. When the V_d for various drugs is expressed as a function of lean body mass rather than body weight characterized by kilograms, differences in drug V_d diminish. When drug dosing is based on the patient's body weight, the real differences in the body composition of patients with CF necessitate higher individual milligram-per-kilogram drug dosing to achieve systemic drug exposure similar to that of patients who do not have CF.[56]

Drug elimination also appears to be enhanced in patients with CF.[53,57] Despite well-characterized CF-induced hepatic dysfunction, particularly in patients with CF who are older than 15 years of age, the CL of many drugs that undergo hepatic metabolism may be unchanged or increased in patients with CF. Emerging data are revealing that the function of phase I mixed-function oxidases is selectively affected; the functional capacity of cytochrome P450 (CYP450) system isoforms CYP1A2 and CYP2C8 appear to be enhanced, whereas CYP2C9 andCYP3A4 are unaffected. With phase II reactions, the activity of glucuronyl transferase, *N*-acetyltransferase, and sulfotransferase can be similar or increased.[58] Moreover, the renal CL of many drugs is increased in patients with CF. The mechanism is unknown, but it does not appear to be related to any disease-associated effect on the activity of the primary renal efflux transporter, P glycoprotein.[59] The clinician must increase the amount and possibly the frequency of individual doses to compensate for the larger V_d and CL, as tolerated by the patient. Regardless of the dosing strategy used, close clinical monitoring for antimicrobial efficacy and safety is necessary.

Additionally, in patients with CF, the amount and composition of sputum, as well as bacterial density, have been shown to reduce the bioactivity of many antibiotics (i.e., inoculum effect).[60–62] These pathophysiologic variables must be considered when devising antibiotic regimens, including increasing systemic doses and attempting topical application through aerosol antibiotic administration.[63,64]

Septic Shock or Burn Injury

Children in septic shock or who are severely burned can suffer dramatic physiologic changes.[65–67] One can assume that any child with hemodynamic changes requiring significant fluid resuscitation or pharmacologic pressor support will be neither physiologically nor pharmacokinetically normal. The timing of physiologic changes is somewhat more characteristic with burns than with septic shock because the burn insult is of defined duration. The first phase in the 48 hours after a severe burn is characterized by an acute decrease in glomerular filtration as a result of hypovolemia and shock, with a rapid shift of intravascular fluid to the interstitial spaces. After 48 hours, with adequate resuscitation, the second phase is characterized by increased cardiac output, increased glomerular filtration (although not tubular secretion), hypoalbuminemia with reduced drug protein binding, and edema. Unfortunately, burned patients frequently sustain hypovolemic renal injury, which can antagonize postburn increased glomerular filtration. Additionally, the function of hepatic CYP450 enzymes appears to be depressed in burned patients. These factors and others have an important impact on drug disposition and require dose adjustments.

Similar changes can be observed in patients with septic shock, with early increases in the V_d of hydrophilic drugs associated with increased capillary leak and fluid resuscitation, as well as organ blood flow associated with hyperdynamic cardiac output. Subsequent infection- and immune-mediated tissue damage can then compromise organ function, including drug metabolism and elimination. The temporal variability of the pathophysiologic changes associated with septic shock and burns makes the PK of antibiotics unpredictable. Nonetheless, some studies have revealed class-dependent patterns that can make antibiotic dosing more rational. Table 291.3 indicates the PK changes observed for various commonly used antibiotics and provides suggested dosing strategies. Ongoing awareness of the patient's physiologic status and further monitoring of serum antibiotic concentrations or secondary markers such as creatinine CL and albumin are required to ensure that the most effective dosing regimens are maintained.

TABLE 291.3

Pharmacokinetic Alterations of Specific Antibiotics With Suggested Dosing Strategies in Patients With Septic Shock or Extensive Burns

Antibiotic	Pharmacokinetic Change	Suggested Dosing Strategy
Aminoglycosides	Generally increased clearance and V_d	1. Administer twice the standard multiple daily dose[a]
		2. Measure drug concentration at end of infusion and 4 hr after end of infusion
		3. If 4-hour concentration is <2 µg/mL (gentamicin, tobramycin) or <5 µg/mL (amikacin), administer another dose; otherwise, estimate V_d and $t_{1/2}$, and administer second dose when trough concentration expected to be at target
		4. Continue dose and schedule from step 3
		5. Confirm therapeutic trough and peak 3 doses later
Glycopeptides (vancomycin, teicoplanin)	Generally increased clearance; fair correlation with CLCr; V_d is not affected	1. Measure CLCr as soon as possible (after initial 48 hr after burn) 2. Administer highest end of standard dose based on shortest dosing interval
		3. Measure peak concentration at end of dosing interval 4. Time the measurement of trough level on CLCr, if available[b]; if unavailable, measure trough before next dose is due

		after a standard short interval
		5. Adjust dose and interval based on serum peaks and troughs[c]
β-Lactams (cefepime,[332] ceftazidime, ticarcillin-clavulanate, piperacillin-tazobactam[333,334])	V_d is substantially increased; total clearance generally is correlated with CLCr; $t_{1/2}$ is variably increased, but initial serum concentrations are less than normal	1. Measure CLCr as soon as possible (after initial 48 hr after burn) 2. Consider 50% increase over highest usual dose 3. Dosing interval depends on CLCr. If higher than normal, choose moderately short interval; if lower than normal, choose long interval
Carbapenems and monopenems (imipenem, meropenem, aztreonam)	Clearance correlates well with CLCr; V_d unchanged to somewhat increased	1. Measure CLCr as soon as possible (after initial 48 hr after burn)
		2. Use high end of standard dose
		3. Dosing interval depends on CLCr; If higher than normal, choose short interval; if lower than normal, choose long interval

[a] Once-daily dosing of aminoglycosides has been shown to result in extended periods of subtherapeutic plasma concentrations in excess of those seen in nonburned patients, thus potentially compromising efficacy, and standard multiple daily dosing carries a significant risk of subtherapeutic peaks. Therefore, higher dose multiple daily dosing is preferred initially.[338]

[b] The standard dose of vancomycin in children with the shortest interval is 15 mg/kg every 6 hours. If CLCr is 100% of normal for age, weight, and sex, measure trough 5 hours after the end of infusion (1 × normal dosing interval). If CLCr is 50% of normal, measure trough 11 hours after the end of infusion (2 × normal dosing interval). If CLCr is 200% of normal, measure trough 2 hours after the end of infusion (0.5 × normal dosing interval).

[c] Based on the pharmacokinetic and pharmacodynamic characteristics of vancomycin, continuous infusion can be an alternative for patients with rapid clearance to avoid excessively large or frequent doses. Clinical data are limited, and the best-targeted serum concentration is not clear, but it is likely at least 8 × MIC, with the understanding that particular caution or alternate therapies should be considered if sustained vancomycin concentrations >30 mg/L are considered necessary.[339–341]

CLCr, creatine clearance; $t_{1/2}$, drug's elimination half-life; V_d, volume of distribution.

Data from references 335 to 337, except where noted.

Basis for Drug-Drug Interactions

Pharmacokinetic Interactions

A drug-drug interaction can exist at any phase of the PK profile (see Fig. 291.1): absorption, distribution, metabolism, or elimination. Frequently, these interactions are predictable qualitatively, if not always quantitatively. For example, knowing that clarithromycin inhibits the same hepatic enzyme responsible for metabolizing cyclosporine leads one to predict that clarithromycin is likely to raise the cyclosporine serum concentration and that a lower dose of cyclosporine may be required. However, actual quantitative adjustment of the cyclosporine dose must be based on measurement of the serum concentration or close monitoring of the patient (or both) for defined end points of efficacy and side effects.

The first step consists of awareness of the possibility of a drug-drug interaction and knowledge of the PK properties of the respective drugs. The second step is assessment of the clinical relevance of a potential interaction. Clinical importance occurs when the amount of free (active) drug in the body is significantly altered such that therapeutic efficacy is compromised or toxicity is increased. An assessment of possible specific influences on each aspect of a drug's disposition profile is outlined in the following sections.

Absorption

The absorption of orally administered drugs can be altered by numerous factors:

1. Alterations in GI motility by pharmacologic or nonpharmacologic means. Intestinal motility can be influenced by the administration of gastrokinetic medications (e.g., metoclopramide, erythromycin) or decreased by drugs with anticholinergic or opiate properties.

2. The presence of food in the GI tract. Food can affect the absorption of many antibiotics. For example, itraconazole tablets and posaconazole liquid are better absorbed in the presence of fatty food, whereas itraconazole solution is better absorbed in the fasting state.

3. Alterations in gastric pH. Drugs that are highly charged cross membranes poorly, including the GI mucosal surface. In the normally acidic environment of the stomach, drugs that are weak acids are nonpolar; weak bases are charged. As the pH increases with the use of antacids, histamine (H_2)-blocking agents, and proton pump inhibitors, weak acids become more polar and are thus absorbed less, whereas weak bases become less polar and are

absorbed more readily. For example, increased gastric and proximal duodenal pH reduces the absorption of cefpodoxime,[68] itraconazole capsules but not solution,[69] oral ampicillin (product insert), and the antiretroviral drugs atazanavir and indinavir.[70] In contrast, absorption of the antiretroviral drug raltegravir is enhanced by concomitant omeprazole, which raises pH.[71] These examples notwithstanding, because most drug absorption occurs in the small intestine, which is buffered, gastric pH generally plays a minor role in the overall bioavailability of orally administered drugs.

4. Binding substances. Fluoroquinolones and tetracyclines are poorly absorbed in the presence of cationic ions such as the bismuth, calcium, aluminum, and magnesium ions found in vitamin supplements and antacids; concomitant use of these medications should be avoided. Such interactions can be avoided by separating administration by a minimum of 2 to 4 hours.

Distribution

Drug interactions influencing distribution can result from interactions with drug displacement from plasma proteins, most notably serum albumin, and with drug transporters. Drug-drug protein displacement interactions represent drug interactions of common clinical concern but of rare clinical significance, specifically, displacement of one drug or substance (e.g., bilirubin) by another drug or substance from its binding site or sites (e.g., albumin) and leading to an increased concentration of free drug. The resultant increased free drug concentration undergoes distribution and CL and also is available for enhanced PD effect. However, *all* the following criteria must be fulfilled before such an interaction becomes problematic:

1. The antibiotic must be highly protein bound (> 80%).

2. It must have a small V_d (<1 L/kg). A larger V_d means that the bulk of the drug is extravascular and is not affected by changes in serum protein binding.

3. The drug must have a long $t_{1/2}$. As drug is displaced from serum protein, it not only becomes biologically active but also becomes

available for distribution to extravascular sites, metabolism, and excretion. For drugs with a short $t_{1/2}$, any displaced excess free drug is quickly redistributed, inactivated, or eliminated from the body, thus promptly reaching a new equilibrium (within 3–5 half-lives). A lower amount of total drug (and thus a larger apparent V_d) characterizes this new equilibrium, and although the free fraction is higher, the absolute concentration of free active drug is the *same* as before. This disposition occurs with all displaced drugs, but the $t_{1/2}$ of the displaced free drug is the most significant factor because it determines the time for the displaced free drug to re-equilibrate. The longer the free drug $t_{1/2}$, the greater is the amount of time that elevated active drug concentrations are available to augment the therapeutic or toxic effects (or both). The implication of a decreased total serum concentration but the same free concentration is that highly protein-bound drugs with therapeutic levels based on the total serum concentrations (e.g., voriconazole[72,73]) can appear falsely subtherapeutic because the active free drug concentration is not being measured. These arguments also apply when patients are profoundly hypoalbuminemic, which has the same effect on free and total drug kinetics as displacement from albumin. The reason is that both displacement and hypoalbuminemia result in reduction of available binding capacity.

4. The antibiotic must have a low therapeutic index (i.e., significant toxicity occurs at a serum concentration only slightly higher than therapeutic concentrations).

Although several antibiotics meet some of the criteria outlined, none meets all of them. Therefore, concern about toxicity caused by the displacement of antibiotics from serum proteins appears to be unwarranted.

The converse question is whether highly protein-bound antibiotics can displace potentially harmful substances that are bound to serum proteins. The area of greatest concern in pediatrics is displacement of albumin-bound bilirubin and subsequent kernicterus in a neonate. The most commonly implicated drugs are the sulfonamide antibiotics and ceftriaxone. The pathophysiology of kernicterus is incompletely understood but is more complex than simple displacement of albumin-bound bilirubin. The only antibiotic that has actually been associated with kernicterus is IV sulfisoxazole,[74] and this may have been a result of the sulfisoxazole diluent in the drug preparation administered. Supporting this inference is the lack of any reported case of kernicterus associated with use of the combination drug trimethoprim-sulfamethoxazole in neonates.[75] Nonetheless, because the development of kernicterus involves the transfer of bilirubin from serum and tissue albumin to brain parenchyma in neonates,[76] especially premature infants, it seems prudent to avoid the use of antibiotics that do or could potentially displace bilirubin unless no other choice is available. Commonly used antimicrobial agents and their ability to displace bilirubin are listed in Table 291.4.[77–79]

TABLE 291.4

Antibiotics Classified According to Their Possible Ability to Displace Bilirubin From Albumin in Cord Blood Serum in Vitro

High[a]	Intermediate	Low	No Data[b]
Cefoperazone	Ampicillin	Aminoglycosides	Acyclovir
Ceftriaxone	Cefonicid	Amoxicillin	Amantadine
Dicloxacillin	Cefoxitin	Aztreonam	Amphotericin B[c]
Sulfamethoxazole	Cephalexin	Cefamandole	Cidofovir
Sulfisoxazole	Erythromycin	Cefazolin	Clindamycin
	Imipenem	Cefotaxime	Fluconazole
	Nafcillin	Ceftazidime	Ganciclovir
	Vancomycin	Cefuroxime	Meropenem
		Ciprofloxacin	Metronidazole
		Penicillin G	Neuraminidase inhibitors
		Piperacillin	Protease inhibitors[c]
		Ticarcillin	Reverse transcriptase inhibitors

[a] Avoid in neonates unless no alternative is available.

[b] Although specific data regarding the ability of these antimicrobials to displace bilirubin are lacking, these drugs appear to be safe in this regard based on clinical experience and a low degree of protein binding.

[c] Infants receiving amphotericin B or the protease inhibitor atazanavir can have elevated total serum bilirubin, but not because of displacement from albumin.

Metabolism

Many drug-drug interactions occur at the level of drug CL, particularly for drugs that undergo metabolism. The CYP450 enzyme system is responsible for the metabolism of many drugs, including antibiotics. These enzymes can be inhibited, induced, or saturated by substrate. For antibiotics that are primarily metabolized by one CYP450 isoform, the potential exists for significant changes in serum concentration, given that CL is either increased or decreased because of changes in enzyme activity. The highest concentration of these enzymes is in the liver, but the intestinal mucosa also contains CYP450 enzymes and is the site of numerous drug-drug interactions that affect bioavailability. To predict a clinically significant drug-drug interaction, therefore, similar questions are asked regarding whether the antibiotic is primarily metabolized by 1 CYP450 isoform or has alternative or parallel metabolic pathways and whether a change in serum concentration would have significance. Specifically, if the serum concentration is lowered, could the antibiotic concentration−time course ratio fall short of the optimal PK-PD–predicted concentration−time course ratio? If the serum concentration is raised, could toxicity occur?

Table 291.5 lists antimicrobial agents that modulate specific CYP450 isoforms that predispose a patient to potential drug-drug interactions when these drugs are coadministered with drugs metabolized by similar pathways. Knowledge of which isoform is primarily responsible for a drug's metabolism provides the clinician with the insight at least to question the possibility of a metabolically based drug-drug interaction. For specific drug-drug interactions, refer to individual agents in Chapter 292.

TABLE 291.5

Antibiotic–Cytochrome P450 Interactions[a]

Isoenzyme	Substrate	Inhibitor	Inducer
1A1	Chloroquine, erythromycin, nitrofurantoin, raltegravir	Atazanavir, ketoconazole, norfloxacin, quinidine	Albendazole, fluconazole, itraconazole, mebendazole, primaquine, **rifampin**
1A2	Albendazole, erythromycin, griseofulvin, pyrazinamide, rifabutin, rifampin, terbinafine	Albendazole, artemesinin, clarithromycin, efavirenz, erythromycin, fluconazole, fluoroquinolones (especially **ciprofloxacin**), isoniazid, ketoconazole, lopinavir, nevirapine, ritonavir, tenofovir	Albendazole, griseofulvin, **rifampin, ritonavir**
1B1	Erythromycin	Doxycycline, ketoconazole	**Rifampin**

2A6	Artemisinin, artesunate, rifampin, zidovudine		**Rifampin**
2B6	Artemisinin, efavirenz, nevirapine, rifampin, ritonavir	Amprenavir, efavirenz, ketoconazole, nelfinavir, ritonavir, nevirapine	Artemisinin, efavirenz, nevirapine, **rifampin, ritonavir**
2C8	Amodiaquine, amprenavir, chloroquine, dapsone, fosamprenavir, quinidine, sulfadiazine, trimethoprim, zidovudine	Chloramphenicol, efavirenz, fluconazole, indinavir, isoniazid, ketoconazole, metronidazole, rifampin, ritonavir, saquinavir, sulfamethoxazole, trimethoprim	Griseofulvin, **rifampin, ritonavir**
2C9	Amprenavir, dapsone, fluconazole, fosamprenavir, metronidazole, quinidine, rifampin, sulfamethoxazole, trimethoprim, terbinafine, voriconazole	Adefovir, atovaquone, chloramphenicol, efavirenz, **fluconazole,** indinavir, isoniazid, ketoconazole, lopinavir, metronidazole, nelfinavir, pyrimethamine, sulfamethoxazole, tenofovir, trimethoprim, voriconazole	Dapsone, nelfinavir, rifapentine, **rifampin, ritonavir**
2C19	Amoxicillin, artemether, chloramphenicol, clarithromycin, dapsone, etravirine, nelfinavir, praziquantel, proguanil, rifampin, terbinafine, voriconazole, zidovudine	Amprenavir, chloramphenicol, clarithromycin, efavirenz, fluconazole, fosamprenavir, indinavir, isoniazid, ketoconazole, lopinavir, probenecid	Artemisinin, **rifampin, ritonavir**
2D6	Chloroquine, rifampin	Chloroquine, efavirenz, fluconazole, isoniazid, lopinavir, mefloquine, nelfinavir, nevirapine, praziquantel, proguanil, quinidine, ritonavir	**Rifampin,** rifapentine
2E1	Dapsone, isoniazid, proguanil, rifampin, sulfadiazine	Isoniazid, itraconazole, ketoconazole, tenofovir	Ciprofloxacin, isoniazid, **rifampin**
3A4, 3A5, 3A7	Albendazole, azoles, artemether, artemesinin, chloroquine, clindamycin, dapsone, erythromycin, HIV protease inhibitors and nonnucleoside reverse transcriptase inhibitors, ivermectin, macrolides and azalides, mefloquine, primaquine, quinidine, rifampin, terbinafine, tetracyclines, trimethoprim, zidovudine	**Azoles,** caspofungin, clindamycin, efavirenz, fluoroquinolones, **HIV protease inhibitors**, isoniazid, **macrolides**, mefloquine, metronidazole, quinidine, quinupristin-dalfopristin, primaquine, sulfamethoxazole, tetracyclines	HIV protease inhibitors and nonnucleoside reverse transcriptase inhibitors, **rifampin,** rifapentine, terbinafine

[a] Currently described interactions are listed in http://bioinformatics.charite.de/supercyp/. Interactions may not be clinically significant, but have been described in vitro. The most significant inhibitors and inducers are shown in **bold.**

Elimination

The primary mechanisms of antibiotic elimination from the body involve elimination via bile, feces, urine, or combinations of these mechanisms. Drugs that are eliminated in the bile are subject to enterohepatic recirculation, which means that they can be reabsorbed into the circulation from drug-containing bile secreted into the intestines, resulting in complex absorption profiles characterized by multiple concentration peaks over the dosing interval. Amoxicillin can lower the effectiveness of oral contraceptives by altering the GI flora, reducing enterohepatic recirculation of the contraceptive, and enhancing elimination. Agents eliminated in urine can be filtered at the glomerular level and secreted at the tubular level. Fortunately, few drugs cause unwanted alterations at these sites. However, any agent that can reduce glomerular filtration (e.g., amphotericin B, cisplatin) can decrease the CL of the concurrently administered and filtered antibiotic, potentially necessitating dose adjustment. A notable example that has been used therapeutically is probenecid, a drug that inhibits the tubular secretion of organic acids by antagonizing the efflux effects of select organic anion transporters (OATs; see the later section on transporters). Probenecid can be coadministered with penicillin to reduce the extent of the antibiotic's tubular secretion and promote its accumulation in the body. This drug is also administered with systemic cidofovir to mitigate toxicity of the drug by reducing intraluminal concentrations. Nevertheless, the lack of adequate guidelines for pediatric dosing of probenecid, the unpredictability of the drug-drug interaction, and the exact amount of drug accumulation and the potential that probenecid can also interfere with in vivo antibiotic distribution (antagonism by probenecid of the organic acid transport used by selected β-lactams into target tissue) preclude the common use of probenecid for this use in children or adults.

Transporters

Transporters important to cellular homeostasis influence the bioavailability, distribution, and elimination of many drugs.[80] Examples of such transporters are P glycoprotein (P-GP), the organic anion transport polypeptides (OATP), and the organic cation transporters (OCTs), which often are associated with drug efflux out of the cell or facilitation of intracellular drug uptake. Transporters are found in many organs and tissues including the intestinal tract, placenta, blood-brain barrier, liver, and kidney and also are subject to induction and inhibition.[81] Drugs can serve as substrates, inhibitors, inducers, or any combination of the 3, thereby resulting in complex interactions that can be difficult to predict quantitatively. Thus changes in the balance of cellular efflux or uptake in the intestine may decrease or increase bioavailability, whereas changes in tissues may affect V_d and drug CL.

Antimicrobial agents that are substrates for the P-GP efflux transporter include select protease inhibitors, erythromycin, and the antifungal drugs ketoconazole and itraconazole. Substrates for OATs include the penicillins and select cephalosporins. Probenecid inhibition of OATP activity is still used as a part of the amoxicillin-probenecid drug combination for uncomplicated *Neisseria gonorrhoeae* (amoxicillin-susceptible) disease.

Pharmacodynamic Interactions

PD interactions can affect efficacy or toxicity, and drugs can interact to diminish or augment either effect. As discussed in Chapter 289, these interactions can be synergistic, additive, indifferent, or antagonistic. Because PD interactions arise from relationships with a drug's mechanisms of action, the clinician must be aware of these mechanisms. The appropriate question is whether the mechanisms of action of a patient's medications are likely to be related in any way. Table 291.6 outlines some frequent examples of each type of PD-based interaction.

TABLE 291.6

Examples of Pharmacodynamic Interactions

Efficacy	Toxicity
INCREASED Numerous examples exist: synergistic activity of β-lactam plus aminoglycoside against enterococci; β-lactam plus β-lactamase inhibitor for extended gram-negative and anaerobic coverage; trimethoprim plus sulfamethoxazole; quinupristin plus dalfopristin	**INCREASED** Two potentially nephrotoxic antibiotics such as vancomycin plus an aminoglycoside can increase the likelihood of renal injury
DECREASED	**DECREASED**

The antiretroviral drugs zidovudine and stavudine are antagonistic when coadministered, likely because of an interaction at the level of intracellular, molecular targets	Probenecid mitigates the nephrotoxicity of cidofovir[342]

Integration of Pharmacokinetic and Pharmacodynamic Principles for Optimal Antibiotic Dosing Regimens

Identification and definition of optimal doses and dosing intervals for antimicrobial agents have eluded clinicians and investigators for decades. This problem can be attributed to the difficulty and delay in measuring outcome, specifically, clinical improvement, microbiologic eradication, or survival. This difficulty in quantifying the effect of antibiotics is in contrast to other classes of drugs used in clinical medicine (e.g., antihypertensive drugs). Substantial research to date has described the PK properties for most antimicrobial drugs used in pediatric practice. The challenge remains to determine objective PD markers or end points that reflect optimal dosing to achieve the desired therapeutic response.[82]

Pharmacodynamic Correlates for Antibacterial Agents

Antibacterial agents influence the life cycle of organisms in various ways. To alter bacterial growth, antibiotics must bind to a cellular target[82–84] (Fig. 291.2). Binding of the drug to its target results in alteration of the normal function of the bacterium and leads to either inhibition of growth or cell death. In addition to the ability of an antimicrobial agent to reach its target site of action (i.e., the receptor), the drug also must possess sufficient affinity for its receptor, and it must achieve a sufficient concentration to affect bacterial function. These pharmacologic characteristics are the primary determinants of antimicrobial activity.

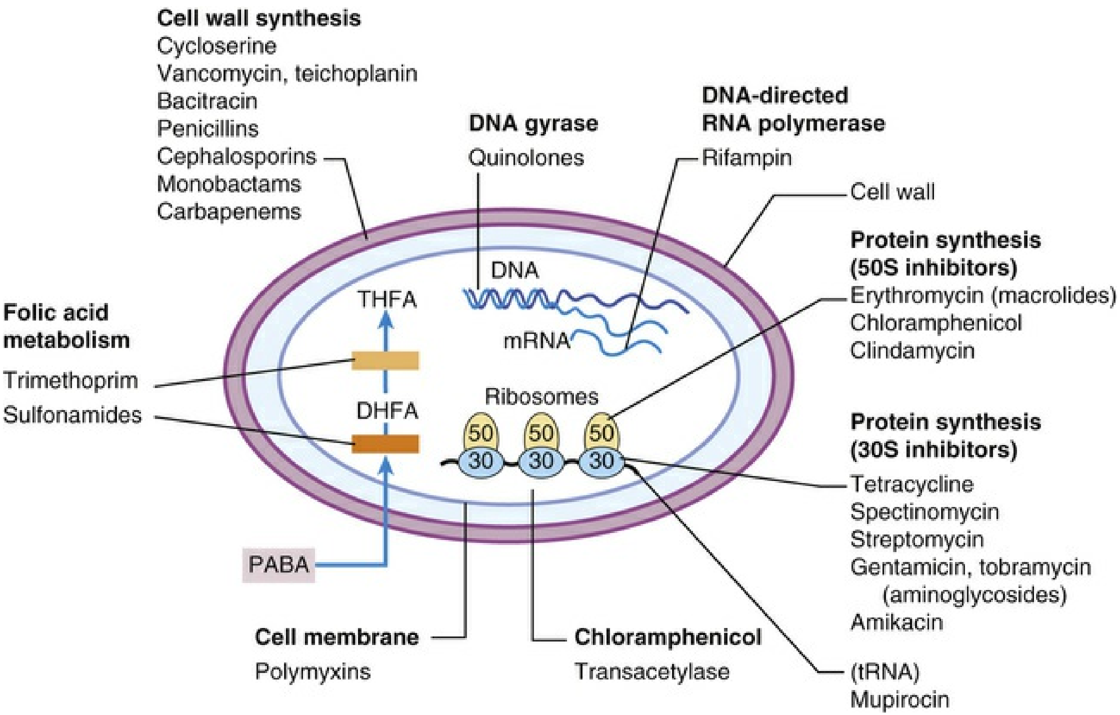

FIGURE 291.2 **Sites of action for major antibacterial drugs. DHFA, dihydrofolate; PABA, *para*-aminobenzoic acid; THFA, tetrahydrofolate.**

(Adapted from Neu HC. The crisis in antibiotic resistance. Science 1992;257:1064–1073.)

Unfortunately, investigators are unable directly to quantify these characteristics clinically. As such, surrogate markers have been developed in an attempt to reflect these crucial cellular interactions. For antibacterial agents, in vitro tests such as the MIC and the minimal bactericidal concentration (MBC) are used as indirect measures of in vivo activity.[85–87] However, these markers do not provide sufficient information on the temporal pattern of exposure of an organism to antimicrobial agents or the antimicrobial concentration that must be achieved relative to the MIC and the MBC to ensure a sufficient therapeutic response.

Consideration of the laboratory procedures used in determining MICs and MBCs raises caution for use as primary indicators of clinical antimicrobial activity. First, measurements of MIC and MBC are obtained in bacterial growth media that are devoid of protein (e.g., represent 100% free active drug), which can have implications for agents that are highly bound to plasma proteins (e.g., >70%). Similar concentrations of free drug at the anatomic site of infection may not be achievable clinically because of extensive protein binding, drug molecular weight, and degree of ionization at pathophysiologic pH. Second, measuring MICs and MBCs usually involves maintaining a constant concentration of free drug for a standard period (generally 18–24 hours). Such a constant concentration simulates a continuous infusion of antibiotic, whereas clinically, antibiotics are usually administered intermittently, which results in peaks and troughs rather than constant concentrations. Third, MICs or MBCs are measured on a standard inoculum of bacteria that may or may not reflect the actual density of bacteria present at the site of infection. Finally, the laboratory procedures used to determine the MIC and MBC do not account for the antimicrobial activity of various host defenses, including immunoglobulins and macrophages.

In vitro susceptibility testing is especially valuable in identifying antimicrobial agents that will be ineffective in eradicating the pathogen. Conversely, a pathogen can appear susceptible to a particular agent from in vitro testing, yet information is lacking on the ability of the agent to achieve the necessary concentrations for a sufficient period at the site of infection to eradicate the pathogen. The immense importance of integrating such data with therapeutic outcome is exemplified by the PK-PD correlates in the successful treatment of bacterial meningitis.[67,82,88] The time course of the drug must be integrated with the concentration at the receptor site to reflect the in vivo antibiotic-bacteria interaction adequately.

As a result of the different mechanisms of inhibiting or killing bacteria and the position of safely achievable concentrations on the concentration-response curve, specific PK-PD properties can be correlated with efficacy (Table 291.7).[89] The first pattern of activity is for drugs with concentrations near the upper, flat portion of the concentration-response curve and that have minimal postantibiotic effect (i.e., ongoing killing after serum concentrations have dropped to less than the MIC). The activity of these drugs depends on the duration of *time that the antibiotic concentration exceeds the MIC* (T >MIC).[82] For these antibiotics, saturation of the bacterial killing rate is observed at certain multiples of the MIC, usually 2 to 4 times, and antibiotic concentrations exceeding this level generally do not achieve greater killing rates. Clearly, the duration that the antibiotic concentration exceeds the MIC of the pathogen is influenced by several factors, including the dosing interval, the pathogen, and the site of infection. Drugs that demonstrate this type of PK-PD relationship are referred to as *time dependent*. Some investigators refer to this class as concentration-independent antibiotics, but this term is not preferable because all antibiotics require a minimal concentration for efficacy. Examples of drugs that exhibit time-dependent killing include all the β-lactams (see Table 291.7).

TABLE 291.7

Classification of Selected Antibacterials Based on Their Pattern of Antimicrobial Activity

Pattern	Drug	Target
Peak/MIC Concentration-dependent killing, prolonged postantibiotic effects	Aminoglycosides	10
	Daptomycin[343]	100 (*Staphylococcus aureus*) 36 (*Streptococcus pneumoniae*) 0.25 (*Enterococcus faecium*)
	Fluoroquinolones	10
	Metronidazole	?
Time >MIC Time-dependent killing, minimal postantibiotic effects	Carbapenems, aztreonam	>20%-40%
	Cephalosporins	>20%-40%
	Penicillins	>40%-60%
AUC/MIC Time-dependent killing, moderate to prolonged persistent antibiotic effects	Azithromycin	25[344]
	Clindamycin	?
	Telithromycin	3[345]
	Dalbavancin[346]	1,000 (*S. aureus*) 100 (*Streptococcus* species)
	Linezolid	80 (or trough > MIC)[347]
	Metronidazole	70[348]
	Macrolides	30[349,350]
	Quinupristin-dalfopristin	?
	Telavancin	219[351]
	Tetracyclines	10
	Tigecycline	18 (gram-positive organisms)[352] 7 (gram-negative organisms)[353]
	Vancomycin	400 (trough ~8 × MIC)[341]

AUC, area under the curve; MIC, minimal inhibitory concentration.

Data are from references 85 and 354 unless otherwise noted.

In contrast, a second pattern of bacterial killing has been characterized for drugs that have concentrations in the steeper portion of the concentration-response curve and that have some degree of postantibiotic effect.[90,91] The bactericidal ability of agents in this group depends on the *peak concentration to MIC* (peak/MIC) within the dosing interval. In other words, the higher the antibiotic peak concentration, the greater is the bacterial kill. Agents that demonstrate this type of PK-PD interface are referred to as *concentration-dependent* or *peak-dependent* antibiotics and include aminoglycosides and fluoroquinolones.

A third class of drugs also has a postantibiotic effect, although it is typically more modest than that of the peak-dependent antibiotics, and these drugs lie near the upper portion of the concentration-response curve. For these drugs it is simply the *AUC/MIC* ratio that best describes activity. These are also called time-dependent drugs, but the moderate postantibiotic effect makes the choice of dose interval less critical than for time-dependent drugs that have little to no postantibiotic effect. Examples of AUC/MIC drugs include vancomycin and azithromycin.

Fig. 291.3 depicts the relationships between drug concentration and effect. The clinical challenge relative to the PK-PD properties of T >MIC and peak/MIC or AUC/MIC is determining the target range for each that correlates with bacteriologic response. These relationships and targets are summarized in Table 291.7.

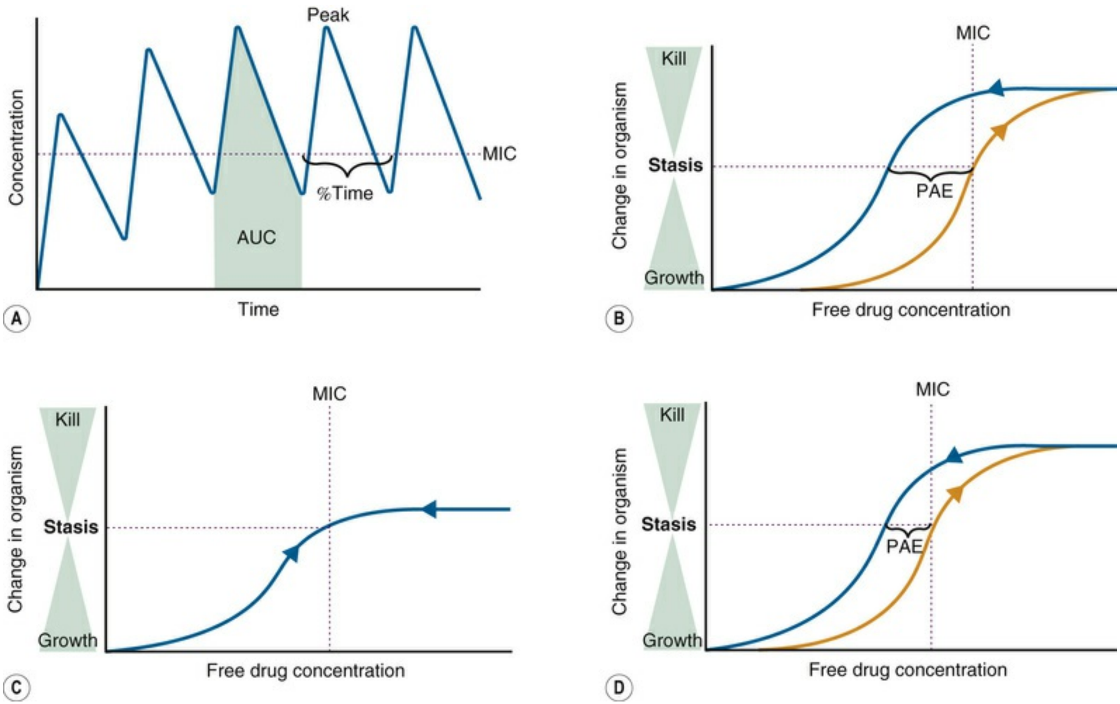

FIGURE 291.3 **Relationship between concentrations and effects for antimicrobials. (A) The 3 classical categories of antimicrobial compounds: peak/minimal inhibitory concentration (MIC), time > MIC, and area under the plasma drug concentration–time curve (AUC)/MIC. (B) The reason that a drug's pharmacokinetic-pharmacodynamic**

linkage may be peak/MIC. As the free drug plasma concentration increases (moving to the right on the x-axis), effect increases in a sigmoidal fashion following the *blue curve.* As the free drug concentration falls (moving to the left on the x-axis), effect diminishes, following the *gold curve.* The effect, in change of organism numbers is shown on the y-axis. Net kill is shown as dashed line above the horizontal. Net growth is shown below it. At the horizontal line stasis occurs, which corresponds to a free drug concentration at the MIC. Note that as the drug concentration falls (along the *red curve*), to less than the MIC, a continued net kill of organism can occur. This is a prolonged antimicrobial effect (PAE), which typifies peak/MIC drugs. The split effect curve (*gold* and *blue*) is termed "negative hysteresis" and can result from delayed action of a drug relative to plasma concentrations, such as a drug's inhibition of microbial protein synthesis. (C) No PAE or negative hysteresis is present, and as soon as drug concentrations fall to less than the MIC, the organism begins to regrow, as is typical of time >MIC agents. (D) Finally, a moderate PAE is present, and the daily dose could be given less frequently as a larger dose (as long as dosing is not so infrequent as to allow regrowth) or more frequently in smaller doses, typical of AUC/MIC agents.

Clinical Utility of Antibiotic Pharmacokinetic-Pharmacodynamic Correlates

The superior ability to predict bacteriologic cure by using integrated PK-PD characteristics, rather than MIC or MBC information solely (see Table 291.7), helps standardize antimicrobial dosing in clinical trials and assists in guiding antimicrobial therapy for individual patients.[82,86,90,92] Furthermore, providing adequate amounts of antibiotic for sufficient periods by optimal dosing based on PK-PD properties also may decrease the rate and extent of bacterial resistance. An appreciation of the PK-PD characteristics of aminoglycosides, combined with a better understanding of their safety profiles, led to once-daily dosing of aminoglycosides that can take advantage of the concentration-dependent killing characteristics of this class of antibiotics (i.e. peak/MIC correlation).[93]

Moreover, in patients with a poor clinical response, an understanding of a particular drug's PK-PD characteristics allows the clinician rationally to assess the potential contribution of suboptimal dosing and to develop an effective, alternative regimen. In their assessment of published data, Craig and Andes[94] demonstrated that the T >MIC for β-lactam antibiotics predicted bacteriologic efficacy with accuracy similar to that of the ratio of middle ear fluid concentration to MIC. Moreover, when the T >MIC exceeded 40% to 50% of the dosing interval, bacteriologic and clinical cure was achieved in 80% to 85% of the patients studied. Although most of the *Streptococcus pneumoniae* isolates in these studies were susceptible to penicillin, the same principles apply to nonsusceptible organisms. For example, conventional amoxicillin dosing (13.3 mg/kg/dose 3 times daily) would be expected to exceed the target T >MIC for penicillin-susceptible *S. pneumoniae*, whereas higher doses (45–50 mg/kg/dose twice daily) often are required to achieve the target T >MIC for many nonsusceptible isolates. It is not the increased dose of amoxicillin per se that correlates with increased efficacy, but rather the longer T >MIC afforded by higher initial concentrations. As an extension of this work, much attention has been paid to modeling improved efficacy of prolonged infusion of β-lactams against resistant gram-negative organisms,[95] and this approach has been prospectively validated in critically ill adults in a randomized study.[89]

An awareness of PK-PD characteristics also permits more sophisticated interpretation of the breakpoints for in vitro susceptibility.[96] In general, guidelines for interpretation are derived from the likelihood of bacteriologic success relative to the MIC of the infecting organism and the projected achievable *serum* concentration of antibiotic. A major exception is the breakpoint reporting for *S. pneumoniae,* for which additional interpretation is based on projected achievable central nervous system concentrations. Thus, if the infection is in an anatomic location other than that for which the breakpoints were derived, the breakpoints can be less relevant.

Pharmacokinetic and Pharmacodynamic Relationships of Other Antimicrobial Agents

Maximizing desirable PD outcomes in combination with minimizing undesirable adverse effects necessarily requires the ability to quantify such end points. Furthermore, an objective index variable must be identified to which therapy can be linked to achieve the therapeutic goals. Although our knowledge of PK-PD relationships for other antimicrobial agents (e.g., antifungal, antiviral, antimycobacterial) is not yet as advanced as for antibacterial agents, progress is being made.[97–99]

Antifungal MICs are determined most reliably for yeasts (e.g., *Candida* and *Cryptococcus*). The value of MICs lies in the assignment of susceptibility breakpoints: drug concentrations higher than which the isolate is considered resistant and lower than which it is considered susceptible. The Clinical Laboratory Standards Institute (CLSI) and the European Committee on Antimicrobial Susceptibility Testing (EUCAST) have established breakpoints for azoles, echinocandins, and flucytosine against *Candida* spp. Although some reliability is similar to MIC breakpoints for bacterial infections,[100] controversy still surrounds the exact thresholds for susceptibility.[101,102] Breakpoints for filamentous fungi, such as *Aspergillus*, still do not exist and will be difficult to generate now that combination therapy is widely used for *Aspergillus* and other filamentous fungal infections.[103] We are only in the early stages of understanding optimal PK-based dosing of antifungal drugs, and Table 291.8 shows the hypothesized relationships and dosing implications.[104]

TABLE 291.8

Proposed Pharmacokinetic-Pharmacodynamic Relationships for Antifungal Drugs

Drug	PK-PD Relationship	Notes
Amphotericin B	Peak/MIC?	Single, large daily doses are more effective than smaller, frequent doses; the dosage is limited by toxicity to a maximum of 1.5 mg/kg/day
Lipid amphotericin B (AmBisome, Abelcet, Amphotec)	Peak/MIC?	As above, but the PK properties of the 3 preparations are different, and more studies are required to determine whether PD differences also exist. Lower toxicity in general permits a higher dosing of 5 mg/kg/day, and tolerability up to 15 mg/kg/day (Ambisome[355]) and 10 mg/kg/day (Abelcet[356]) has been reported, but added efficacy at the higher doses has not been demonstrated and may result in increased nephrotoxicity[357]
Fluconazole	AUC/MIC	Optimal dosing is 6 mg/kg/day IV or PO for susceptible isolates and 12 mg/kg/day for dose-dependent isolates. A loading dose of 25 mg/kg on day 1 should be strongly considered in infants.[358] Doses >12 mg/kg offer unproven additional benefit and increase the risk of toxicity. A dose-MIC ratio of >50 or an AUC/MIC ratio of >25 have been suggested as targets[359]

Itraconazole	AUC/MIC	Target trough concentrations of >0.5 mg/L are recommended[360]
Posaconazole	AUC/MIC	Concentrations demonstrate high interpatient variability; in 2 pivotal phase 3 studies analyzed by the FDA, a plasma concentration of >0.35 mg/L 3–5 hr after dosing on day 2 was predictive of a concentration of >0.70 mg/L at the same time on day 7, which was associated with *prevention* of invasive fungal infections.[360] Another study reported best *treatment* outcomes with average concentrations of >1.25 mg/L.[361] In practice such concentrations are difficult to achieve in children with the suspension[362]; however, the newer delayed-release tablet formulation (approved for ≥13 years of age) has greatly enhanced absorption, and such concentrations are easier to obtain
Voriconazole	AUC/MIC	Target trough concentrations of >1.0 mg/L have been associated with survival benefit in children[7]
Flucytosine	T>MIC	In vitro data suggest that peak efficacy occurs at a serum concentration–MIC ratio of 4 : 1. No data exist on the most effective duration of serum concentration higher than the MIC. If toxicity is problematic (typically with peak >100 mg/L), smaller, more frequent doses or even continuous infusion may be more effective, but human data are lacking. Usual peaks are 30–100 mg/L[363]
Echinocandins (caspofungin, micafungin, anidulafungin)	AUC/MIC	Clinical data are lacking, but in vitro and animal models suggest that for *Candida* species, a free drug AUC/MIC ratio of 5–20 (high end for *C. albicans*, lower for *C. parapsilosis*) may be adequate,[364] which is an AUC/MIC ratio of 3,000 in patients.[365] For *Aspergillus* species, the target is a free C_{max}/MEC ratio of approximately 10[366]

AUC, area under the curve; C_{max}, maximal concentration; FDA, Food and Drug Administration; IV, intravenously; MEC, minimum effective concentration, which is the minimum amount of drug to cause transition to a compact rounded hyphal form; MIC, minimal inhibitory concentration; PD, pharmacodynamic; PK, pharmacokinetic; PO, orally.

PK-PD dosing for antiviral drugs, as shown in Table 291.9, has been most commonly applied to therapy for human immunodeficiency virus (HIV) infection. The concept of MIC determination translates as the inhibitory concentration, or IC_{xx}, where xx is the percentage of viral strains within a particular species for which replication is inhibited in vitro at drug concentration IC. Numerous studies have demonstrated a dose-response relationship for both protease inhibitors and nonnucleoside reverse transcriptase inhibitors and have identified threshold trough serum concentrations, or AUC, greater than which efficacy is improved (as measured by the reduction in viral load and increased $CD4^+$ T-lymphocyte count). Studies also have demonstrated the safety and feasibility of antiretroviral therapeutic regimens tailored to specific patients to maintain serum drug concentrations within a predetermined range, although efficacy studies are yet to come.

TABLE 291.9

Pharmacokinetic-Pharmacodynamic Targets for Antiretroviral and Antiviral Drugs Based on Clinical Data

Drug	**Target C_{min} (ng/mL)**	**Notes**
NONNUCLEOSIDE REVERSE TRANSCRIPTASE INHIBITORS		
Efavirenz	1,000	
Etravirine	275 (81–2,980)	No efficacy target established; value is median (range) from clinical studies
Nevirapine	3,000	
PROTEASE INHIBITORS		
Atazanavir	150	
Darunavir	3,300 (1,255–7,368)	No efficacy target established; value is median (range) from clinical studies in adults given 600 mg twice daily
Fosamprenavir	400	Measured as amprenavir
Lopinavir	1,000	
Nelfinavir	800	Parent drug plus M8 active metabolite
Tipranavir	20,500	Not suggested for PI-naïve patients
ENTRY INHIBITOR		
Maraviroc	50	Not suggested for treatment-naïve patients
INTEGRASE STRAND INHIBITOR		
Raltegravir	72 (29–118)	No efficacy target established; value is median (range) from clinical studies in adults given 600 mg twice daily
NONANTIRETROVIRAL		
Ganciclovir[105]	AUC 35–50 µg/mL/hr	For prevention of CMV infection

AUC, area under the curve; C_{min}, minimal concentration; CMV, cytomegalovirus; PI, protease inhibitor.

Data on antiretroviral agents from Panel on Antiretroviral Therapy and Medical Management of HIV-Infected Children. AIDSinfo. Guidelines for the Use of Antiretroviral Agents in Pediatric HIV Infection. 2015. www.aidsinfo.nih.gov.

For non-HIV viral infections, some data suggest that the acyclovir effect is time dependent and that if the serum drug concentration remains higher than the IC_{50} of herpes simplex virus or varicella-zoster virus for at least 12 hours per day, clinical efficacy is maximized. Ganciclovir has been reported to have near-maximal efficacy to prevent cytomegalovirus infection when a target AUC of 35 to 50 µg/mL per hour is reached, with a concomitant 10% to 20%, and 30% to 50% probability of the patient's developing neutropenia and leukopenia, respectively.[105]

Future Considerations

Increasingly, drug dosing will be based on achieving PK-PD targets in individual patients rather than the traditional population-based recommendations of dosing ranges. Therefore studies of new antimicrobial agents must include an assessment of PK-PD relationships. The ongoing challenge in pediatrics is to ensure that the determination of these important surrogate markers or end points incorporates the important changes that occur with increasing age. Box 291.1 synthesizes the information presented in this chapter into questions that a thorough clinician should consider for every patient to whom antibiotics are to be administered. Box 291.2 provides a listing of useful websites for additional information.

Box 291.1

Important Pharmacokinetic-Pharmacodynamic Issues to Consider When Determining the Dose of Antibiotics

What is the known or suspected target pathogen?

What is the minimal inhibitory concentration of available antibiotics for the pathogen? Will adequate concentrations of the drug be distributed to all infected sites?

Are there any characteristics of the patient that will alter the usual pharmacokinetic properties of the drug?

What process best describes the antibiotic antibacterial activity: time dependent or concentration dependent?

Based on the pharmacokinetic-pharmacodynamic correlate, how often should the antibiotic be administered?

With a suboptimal clinical response, should the individual dose be increased, administered more frequently, or both? Should a different drug be used?

APPENDIX 291.1 Usual Dosing, Therapeutic Targets, and Suggestions for Maintenance Dosing of Selected Antimicrobial Agents in Patients With Impaired Renal Function[a]

Drug (Route)	**Usual Dosing: Maintenance *(Daily Max)***	**Adjustment of Usual Dosing for Renal Failure GFR (mL/min/1.73 m^2)[b]**			**Adjustment for Dialysis[c]**
		>60–90	**30–60**	**<30**	
AMINOGLYCOSIDES[d]					
Amikacin (IM, IV)[108,112–117]	5–7.5 mg/kg q8h	60%–90% q12h	30%–70% q12–18h	20%–30% q24–48h	H: 66% after H
					P: 15–20 mg/L IP
					C: As for CLCr 30–60
Gentamicin (IM, IV)[114,118–121,127–130]	2.5 mg/kg q8h	60%–90% q8h	30%–70% q12h	20%–30% q24–48h	H: 66% after H
					P: 3–4 mg/L IP
					C: As for CLCr 30–60
Streptomycin (IM, IV)[114,122–124]	20–40 mg/kg q24h *(2 g/day)*	Usual dosing	100% q24–72h	100% q72–96h	H: 50% after H
					P: 20-40 mg/L IP
					C: As for CLCr 30–60
					P: 3–4 mg/L IP
					C: As for CLCr 30–60

Tobramycin	2.5 mg/kg q8h	60%–90% q8h	30%–70% q12h	20%–30% q24–48h	H: 66% after H P: 3–4 mg/L IP C: As for CLCr 30–60
CEPHALOSPORINS[e]					
Cefaclor (PO)[125]	10–20 mg/kg q12h *(1.5 g/day)*	Usual dosing	Usual dosing	50% q8h	H: 50–75% q8h P: No significant clearance C: Usual dosing
Cefadroxil (PO)[126]	15 mg/kg q12h *(2 g/day)*	Usual dosing	100% q24h	100% q48h	H: 100% q48h P: No significant clearance C: As for CLCr 30–60
Cefazolin (IV)[127–130]	20–35 mg/kg q8h *(12 g/day)*	Usual dosing	100% q12h	100% q24h	H: 100% q24h P: 15 mg/kg IP q24h C: As for CLCr 30–60
Cefdinir (PO)[131,132]	14 mg/kg q24h *(600 mg/day)*	Usual dosing	Usual dosing	50% q24h	H: 50% q48h P: No significant clearance C: As for CLCr 30–60
Cefepime (IV)[127,133–135]	50 mg/kg q8–12h *(6 g/day)*	100% q12h	100% q16–24h	100% q24–48h	H: 50% q24h P: 15 mg/kg IP q24h C: As for CLCr >60–90
Cefixime (PO)[136]	8 mg/kg q24h *(400 mg/day)*	Usual dosing	75% q24h	50% q24h	H: 75% q24h P: No significant clearance C: As for CLCr 30-60
Cefotaxime[f] (IV)[137,138]	50–75 mg/kg q6–8h *(12 g/day)*	Usual dosing	Usual dosing	50% q6–8h	H: 50% q6–8h P: 500 mg IP q24h C: As for CLCr 30–60
Cefoxitin (IV)[139,140]	20–40 mg/kg q6h *(12 g/day)*	100% q8h	100% q8–12h	100% q24–48h	H: 100% q24–48h P: No significant clearance C: As for CLCr 30–60

Cefpodoxime (PO)[141–143]	5 mg/kg q12h *(800 mg/day)*	Usual dosing	Usual dosing	50% q12h	H: 50% q12h P: No significant clearance C: As for CLCr 30–60
Cefprozil (PO)[144]	15 mg/kg q12h *(1 g/day)*	Usual dosing	Usual dosing	100% q24h	H: 100% q24h P: Significant clearance unlikely C: Likely as for CLCr 30–60
Ceftaroline[g] (IV)[145]	>12y: 8 mg/kg q12h *(1.2 g/day)*	Usual dosing	50%–75% q12h	50% q12h	H: 50% q12h P: No significant clearance C: As for CLCr 30–60
Ceftazidime (IV)[130,146–150]	50 mg/kg q8h *(12 g/day)*	Usual dosing	100% q12h	100% q24h	H: 100% q24h P: 50% IV q24h OR 125 mg/L continuous IP OR 15–20 mg/kg q24h IP C: 50–75% q12h
Ceftriaxone (IV, IM)[151–154]	50–100 mg/kg/day divided q12–24h *(4 g/day)*	Usual dosing	Usual dosing	Usual dosing	H: Usual dosing P: 50 mg/kg IP q24h C: Usual dosing
Cefuroxime sodium (IV)[147]	35-50 mg/kg q8h *(6 g/day)*	Usual dosing	100% q8–12h	100% q24h	H: 100% q24h P: 15 mg/kg IP q24h C: As for CLCr 30–60
Cefuroxime axetil (PO)[147,155]	15 mg/kg q12h *(3 g/day)*	Usual dosing	100% q12h	100% q24h	H: 100% q24h P: No significant clearance C: As for CLCr 30–60
Cephalexin[h] (PO)[156]	25 mg/kg q6h *(4 g/day)*	Usual dosing	Usual dosing	50% q6h	H: 50% q6h P: No significant clearance C: Usual dosing
PENICILLINS					

Amoxicillin (PO)	25–90 mg/kg/day divided q8–12h *(4 g/day)*	Usual dosing	Usual dosing	100% q12–24h	H: 100% q24h P: Significant clearance unlikely C: Usual dosing
Amoxicillin with or without clavulanic acid (PO) (doses in amoxicillin)	20–45 mg/kg/day 90 mg/kg/day (ES-600 formulation) divided q8–12h *(1.75 g/day amoxicillin)*	Usual dosing	Usual dosing	100% q12–24h	H: 100% q24h P: Significant clearance unlikely C: Usual dosing
Ampicillin with or without sulbactam (IV, IM)[157,158] (doses in ampicillin)	25–50 mg/kg q6h *(12 g/day ampicillin)* *(8 g/day ampicillin-sulbactam)*	Usual dosing	100% q8h	100% q12h	H: 100% q24h P: 100% q12h IP C: Usual dosing
Dicloxacillin (PO)	6.25 mg/kg q6h *(2 g/day)*	Usual dosing	Usual dosing	Usual dosing	H/P: No significant clearance C: Usual dosing
Nafcillin[i] (IV)[159]	25–50 mg/kg q6h (12 g/day)	Usual dosing	Usual dosing	Usual dosing	H/P: No significant clearance C: Usual dosing
Oxacillin[j] (IV)	25–50 mg/kg q6h *(12 g/day)*	Usual dosing	Usual dosing	Usual dosing	H/P: No significant clearance C: Usual dosing
Penicillin G (IV)	100–300 kU/kg/day divided q4–6h *(24 MU/day)*	Usual dosing	50% q4–5h	50% q8h	H: 50% q8h P: No significant clearance C: 50% q4–5h
Penicillin VK (PO)	25–50 mg/kg/day divided q6–8h *(2 g/day)*	Usual dosing	50% q4–5h	50% q8h	H: 50% q8h P: No significant clearance C: 50% q4–5h
Piperacillin and tazobactam (IV)[160–164] (doses in piperacillin)	2–9 mo: 80 mg/kg q8h >9 mo: 100 mg/kg q8h >40 kg: 3 g q6h *(16 g/day)*	Usual dosing	66% q6–8h	66% q8h	H: 66% q12h + 20% after H P: No significant clearance and IP tazobactam

					not well absorbed C: As for CLCr 30–60
Ticarcillin and clavulanate (IV)[165,166]	50 mg/kg q4–6h *(18 g/day)*	66% q4–6h	66% q8h	66% q8–12h	H: 66% q12h + 100% after H P: 100% q12h IV C: As for CLCr 30–60
MONOBACTAM					
Aztreonam (IV)[167–169]	30–40 mg/kg q8h *(8 g/day)*	Usual dosing	50%–75% q8h	25% q8h	H: 25% q8h + 12.5% after H P: 100% q8h IP or 25% q8h IV C: As for CLCr 30–60
CARBAPENEMS					
Doripenem[k] (IV)[170]	3 mo–2 yr: 20 mg/kg q8h *(3 g/day)*	Usual dosing	50%–75% q8h	50%–75% q12h	H: Likely similar to other carbapenems P: Significant clearance unlikely C: As for CLCr 30–60
Ertapenem (IV)[171–173]	<13 yr: 15 mg/kg q12h ≥13 yr:1 g q24h *(1 g/day)*	Usual dosing	Usual dosing	50% q12h	H: 50% q12h + 15% after H if H <6h after last dose P: Significant clearance unlikely C: Likely as for CLCr 30–60
Imipenem[l] (IV)[174–183]	15–25 mg/kg q6h *(4 g/day)*	Usual dosing	50% q8h	50% q12h	H: 50% q12h + 25% after H if H <6 hr after last dose P: No significant clearance C: As for CLCr 30–60
Meropenem (IV)[184–193]	20–40 mg/kg q8h *(6 g/day)*	Usual dosing	100% q12h	50% q12–24h	H: 50% q24h; *Or* 100% q48h P: No significant clearance

					C: As for CLCr 30–60
FLUOROQUINOLONES					
Ciprofloxacin (IV, PO)[194–197]	10–20 mg/kg q12h *(1.5 g/day)*	Usual dosing	50% q12h	50% q18h	H: No significant clearance P: No significant clearance C: As for CLCr 30–60
Levofloxacin[198–206] (IV, PO)	<5 yr: 10 mg/kg q12h ≥5 yr: 10 mg/kg q24h *(750 mg/day)*	Usual dosing	50% q24h	50% q48h	H: No significant clearance P: No significant clearance C: As for CLCr 30–60
Moxifloxacin[m] (IV, PO)[207,210,211]	10 mg/kg q24h *(400 mg/day)*	Usual dosing	Usual dosing	Usual dosing	H: No significant clearance P: No significant clearance C: Significant clearance unlikely
MACROLIDES AND LINCOSAMIDES					
Azithromycin (IV, PO)[212]	5–12 mg/kg q24h *(0.5 g/day 2 g/single dose PO)*	Usual dosing	Usual dosing	Usual dosing	H/P/C: Usual dosing
Clarithromycin (PO)	7.5 mg/kg q12h *(1 g/day)*	Usual dosing	Usual dosing	50% q12h	H/P/C: Significant clearance unlikely
Clindamycin (IM, IV)[213]	20–40 mg/kg divided q8h *(4.8 g/day)*	Usual dosing	Usual dosing	Usual dosing	H/P/C: Usual dosing
Clindamycin (PO)	10–40 mg/kg divided q6–8h *(1.8 g/day)*	Usual dosing	Usual dosing	Usual dosing	H/P/C: Usual dosing
Erythromycin[n] (PO)[214]	12.5 mg/kg q6h *(4 g/day)*	Usual dosing	Usual dosing	Usual dosing	H/P/C: Usual dosing
Telithromycin (PO)	No data *(800 mg/day)*	Usual dosing	Usual dosing	75% q24h	H: 75% q24, after dialysis on dialysis days P: Significant clearance unlikely C: Usual dosing

TETRACYCLINES					
Doxycycline[o] (IV, PO)[215]	1–2 mg/kg q12h *(200 mg/day)*	Usual dosing	Usual dosing	Usual dosing	H/P/C: No significant clearance
Tigecycline[p] (IV)	8–11 yr: 1.2 mg/kg q12h 12–17 yr: 50 mg q12h *100 mg/day*	Usual dosing	Usual dosing	Usual dosing	H/P/C: No significant clearance
OXAZOLIDINONES					
Linezolid (IV, PO)[216–220]	10 mg/kg q8h *(1.2 g/day)*	Usual dosing	Usual dosing	Usual dosing	H: Usual dosing P: Significant clearance unlikely C: Usual dosing
Tedizolid (IV, PO)	No data *(200 mg/day)*	Usual dosing	Usual dosing	Usual dosing	H: Usual dosing P: Significant clearance unlikely C: Usual dosing
OTHER ANTIBACTERIAL AGENTS					
Chloramphenicol (IV)[221,222]	12.5–25 mg/kg q6h *(4 g/day)*	Usual dosing	Usual dosing	Usual dosing	H: Usual dosing P/C: No significant clearance
Daptomycin[q] (IV)[223,229–232]	2–6 yr: 12 mg/kg q24h 7–17 yr: 7–9 mg/kg q24h *(6 mg/kg/day)*	Usual dosing	Usual dosing	100% q48h	H: 100% q48h P:100% q48h; *Or* 7 mg/kg IP q24h C: 8 mg/kg IV q48h
Metronidazole[r] (IV, PO)[233–235]	7.5–15 mg/kg q8h *(4 g/day)*	Usual dosing	Usual dosing	75% q6h	H: Usual dosing P: No significant clearance C: Usual dosing
Nitrofurantoin (PO)	1–2 mg/kg q6h *(400 mg/day)*	Usual dosing	Avoid	Avoid	H/P/C: avoid
Quinupristin-dalfopristin[s] (IV)[236,237]	7.5 mg/kg q8h *(22.5 mg/kg/day)*	Usual dosing	Usual dosing	Usual dosing	H/P/C: No significant clearance
Trimethoprim-sulfamethoxazole (IV, PO)[238–240]	4–6 mg/kg q12h	Usual dosing	Usual dosing	100% q12–24h	H: 100% q24h
	Pneumocystis: 5 mg/kg q6–8h	Usual dosing	100% q8h	100% q12–24h	P: No significant clearance C: As for CLCr 30–60

	(20 mg/kg/day)				
Vancomycin[t] (IV)[167,241–245]	15 mg/kg q6h *(2 g/day)*	100% q12–24h	10 mg/kg q24–96h	10 mg/kg q4–10 days	H: 10 mg/kg after H P: 50–100% IP q24h C: As for CLCr 30–60
ANTITUBERCULOUS AGENTS					
Ethambutol (PO)[246–248]	15–25 mg/kg q24h *(2.5 g/day)*	Usual dosing	Usual dosing	100% q48h	H: 100% q48h P: No significant clearance C: Likely usual dosing
Ethionamide (PO)[249]	15–20 mg/kg q24h *(1 g/day)*	Usual dosing	Usual dosing	50% q24h	H: 50% q24h P: No significant clearance C: Likely usual dosing
Isoniazid (IV, PO)[247,250–252]	10–20 mg/kg q24h *(300 mg/day)*	Usual dosing	Usual dosing	Usual dosing	H/P/C: Usual dosing
Para-aminosalicylic acid (PO)[122,249]	100–150 mg/kg q12h *(10 g/day)*	Usual dosing	Usual dosing	Usual dosing	H/P/C: Usual dosing
Pyrazinamide[u] (PO)[122,247,250,253,254]	15–30 mg/kg q24h *(2 g/day)*	Usual dosing	Usual dosing	100% q48–72h	H: As for CLCr <10 P: As for CLCr <10 C: No data
Rifampin (IV, PO)[122,247,250]	10–20 mg/kg q12h *(600 mg/day)*	Usual dosing	Usual dosing	Usual dosing	H/P/C: No significant clearance
ANTIFUNGAL AGENTS					
Polyenes					
Amphotericin B (IV)	0.5–1.5 mg/kg q24h *(1.5 mg/kg/day)*	Usual dosing	Usual dosing	100% q24–48h	H/P/C: No significant clearance
AmBisome (liposomal amphotericin B) (IV)	3–5 mg/kg q24h *(7.5 mg/kg/day)*	Usual dosing	Usual dosing	100% q24–48h	H/P/C: No significant clearance
Abelcet, Amphotec (lipid amphotericin B) (IV)	5 mg/kg q24h *(5 mg/kg/day)*	Usual dosing	Usual dosing	100% q24–48h	H/P/C: No significant clearance
Azoles

Ribavirin (PO)	7.5 mg/kg q12h *(15 mg/kg/day)*	Usual dosing	Avoid	Avoid	H/P/C: Avoid

[a] Package inserts and several review articles[106–110] on antibiotic dosing in renal failure and the various modes of dialysis were consulted for each drug. Recommendations are a synthesis of these sources and the pharmacokinetic characteristics of each drug; where available, supplemental references are included. Data are based primarily on studies in adults because very few pediatric studies are reported in any published source. Usual doses are for children with normal renal function beyond the neonatal period and for maintenance of systemic drug levels after an initial loading dose (which is typically standard in patients with impaired renal function). Doses herein can differ from those recommended by manufacturers (see package inserts) and in many cases are not approved for children.

[b] The preferred method for estimating GFR in children is the revised Schwartz formula: GFR (mL/min/1.73 m^2) = 0.413 Height (cm) / Plasma creatinine (mg/dL).[111] This formula is most accurate in the GFR range of 15 to 75 mL/min/1.73 m^2, and values outside this range should be reported only as less than or below these limits.

[c] These dose projections are only guidelines and are based on standard intermittent

hemodialysis 3 times weekly, continuous peritoneal ambulatory dialysis with 3 to 4 daily exchanges, and continuous renal replacement with ultrafiltration rates of approximately 1 L/hr. The advent of high-flux or extended intermittent hemodialysis, earlier use of continuous renal replacement in critically ill patients who have residual renal function, and the myriad of settings possible for all forms of ultrafiltration and dialysis make the possibility of clinically significant underdosing or overdosing very real indeed. Measurement of serum drug concentrations must be used when feasible. “No significant clearance” means that the drug should be dosed according to the recommendation for a given degree of renal failure, without regard to dialysis schedule. For intermittent hemodialysis, unless “no significant clearance” is noted, dialysis should always be timed to give the scheduled dose at the end of the dialysis session. If this is not possible, clinicians must use their best judgment about administering a supplemental dose after dialysis, depending on when the next regular dose is due and the relative risks of drug toxicity versus subtherapeutic concentrations. Peritoneal dialysis, as discussed in the text, removes most drugs poorly from blood; therefore, unless indicated, oral or intravenous drugs should be administered according to the patient's underlying renal function. However, many drugs can achieve therapeutic serum concentrations when administered intraperitoneally; hence recommendations for this route are included.

[d] Serum drug concentrations should be monitored. Concurrent administration with penicillins can result in subtherapeutic gentamicin or tobramycin. Peritoneal absorption increases with inflammation. Doses for once-daily aminoglycoside regimens in patients with normal renal function generally should not be used in patients with compromised renal function; hence they are not reported here.

[e] Peritoneal absorption of cephalosporins is generally good.

[f] Active metabolite of cefotaxime also accumulates in ESRD. The dose should be further reduced for hepatic and renal failure.

[g] Usual dose of ceftaroline is if the patient is >12 years of age; not approved for patients <18 years of age.

[h] To treat urinary tract infection in ESRD with cephalexin, the usual dose should be administered.

[i] Drugs with renal and hepatic excretion such as nafcillin require little change unless both mechanisms are impaired.

[j] Drugs with renal and hepatic excretion such as nafcillin or oxacillin require little change unless both mechanisms are impaired.

[k] Doripenem is not approved for patients <18 years of age. Doses in children appear to result in similar exposure as in adults receiving 1 g IV q8h. [170]

[l] Imipenem neurotoxicity can occur, especially in ESRD.

[m] Moxifloxacin is not approved for patients <18 years of age. Dose recommendation is based on a study,[207] allometric scaling from adult dose, and a case report.[208] In addition, a case report noted a dose of 13 mg/kg q24h used in an infant.[209] The single study showed that 10 mg/kg resulted in slightly lower exposure than the adult dose of 400 mg,[207] so the dosing remains uncertain.

[n] Ototoxicity from erythromycin can occur with prolonged high doses in ESRD.

[o] Doxycycline is the preferred member of the tetracycline class for use in patients with impaired renal function.

[p] Tigecycline is not approved in children <12 years of age.

[q] Daptomycin is not approved for use in children. The doses listed are planned for studies, although these studies are not currently enrolling.[223] Some reports have noted dosing and pharmacokinetics in children at the same dose as for adults (4–6 mg/kg q24h), although the exposure can be lower in the pediatric patients relative to the adults.[224–226] Investigators have even reported the use of intraventricular daptomycin in a toddler at a dose of 2.5 mg in 5 mL normal saline, administered every 24 hours through ventriculostomy that was locked for 30 minutes after administration and then reopened.[227] One study found that daptomycin failure was independently associated with severe renal failure, thus raising the question whether the recommended dosing for these patients is suboptimal.[228]

[r] Dosage adjustment of metronidazole is necessary because the metabolite accumulates in ESRD, although this is cleared by hemodialysis and continuous renal replacement.

[s] Microbiologically active metabolites of quinupristin-dalfopristin can accumulate in renal failure and can be cleared by dialysis.

[t] Serum vancomycin concentrations should be monitored.

[u] Serum pyrazinamide concentrations are the best guide.

[v] Iavuconazole is dosed as the prodrug isovuconazonium sulfate; 372 mg of the prodrug is equivalent to 200 mg of active isavuconazole.

[w] β-Cyclodextrin, the vehicle for the oral liquid and intravenous itraconazole and voriconazole preparations, is cleared by the kidneys and accumulates in patients with significant renal failure after intravenous administration; oral dosing is therefore preferred in patients with CrCL<50. Absorption of liquid itraconazole is superior to the capsules; thus liquid itraconazole is preferred for oral therapy.

[x] Posaconazole dosing in children has not been established, but in children 8 to 13 years of age, 200 mg of suspension 4 times daily or 400 mg twice daily (800 mg/day) provided exposure similar to that observed in adult dosing. For patients 13 to 17 years of age, 200 mg 3 times daily (600 mg/day) provided similar exposure. The newer IV and DR oral tablets both achieve much better plasma concentrations in adults, but pharmacokinetic results and dosing recommendations are not yet available for children <13 years of age. For children >13 years of age, adult doses are used.

[y] Anidulafungin is not approved in children, but 1.5 mg/kg/day in infants to adolescents results in exposures similar to those in to adults who receive 100 mg/day.[267,268]

[z] Serum flucytosine concentrations should be monitored; bone marrow suppression is more common in azotemic patients.

[aa] Terbinafine is not approved in children. The usual dosing provided here has been shown to reproduce adult exposures from 250 mg/day.[271,272]

[bb] Acyclovir impairs urate secretion and can cause gout; uric acid levels should be monitored.

[cc] No pediatric dose has been established for cidofovir. Dosing ranging from 5 mg/kg weekly (induction) followed by 3 to 5 mg/kg weekly to biweekly (maintenance), to 1 mg/kg thrice weekly, to 0.25 to 1 mg/kg every other week have been used for adenovirus, cytomegalovirus, and polyomavirus infections in children.[279–282] Although the package insert states that the drug is contraindicated in renal failure, the reported dosing guidelines were developed with the intent to change the label.[283]

[dd] The maintenance ganciclovir dose is half the induction dose; bone marrow suppression is more common in azotemic patients.

[ee] Amantadine neurotoxicity is more common in ESRD.

[ff] Peramivir is not licensed for use in patients <18 years of age.

[gg] These doses are for prophylaxis only. Rimantidine is not indicated for influenza treatment in patients <16 years of age.

[hh] Indinavir is not approved in children. Doses shown to approximate adult exposures include 50 mg/kg, 500 mg/m^2, and 600 mg/m^2, all administered every 8 hours.[320–326]

BSA, body surface area; C, continuous renal replacement; CLCr, creatinine clearance (calculated or measured); DR, delayed-release; EC, enteric-coated; ESRD, end-stage renal disease; GFR, glomerular filtration rate; H, intermittent hemodialysis; HIV, human immunodeficiency virus; IM, intramuscular(ly); IP, intraperitoneal(ly); IV, intravenous(ly); kU, thousand units; MU, million units; P, continuous peritoneal dialysis; PO, oral(ly).

292

Antimicrobial Agents

Jason B. Sauberan, John S. Bradley

Antimicrobial agents are essential in the therapy of bacterial infections. The approach to antimicrobial therapy is outlined in Chapter 289, which provides the clinician with an overview of the selection of agents based on the characteristics of infected children with respect to their pathogens and antibiotic susceptibilities, sites of infection, antibiotic tissue exposure, comorbidities, and a consideration of the benefits versus the risks of antimicrobial therapy. In this chapter, the agents themselves are discussed, providing a background on mechanism of action, spectrum of antibacterial activity, antibiotic resistance, and current clinical use. A more detailed discussion of specific infections is found in each chapter describing that infection. An in-depth discussion of antibiotic resistance and the ways to detect resistance is presented in Chapter 290. Pharmacokinetic-pharmacodynamic basis of optimal antibiotic therapy is discussed in Chapter 291. Table 292.1 provides a summary of the pharmacokinetics, tissue distribution, metabolism, and excretion of commonly used antimicrobial agents within each of the antibiotic classes. Table 292.2 provides the spectrum of activity of each antibiotic. Appendices 292.1 and 292.2 provide dosages of antibiotics. Chapters related to specific pathogens also should be consulted.

TABLE 292.1

Pharmacokinetics, Tissue Distribution, Metabolism, and Excretion of Antimicrobial Agents

Agent	Oral Bioavailability	Protein Binding	Body Distribution and CSF Penetration	Metabolism	Excretion
AMINOGLYCOSIDES					
Gentamicin, amikacin, tobramycin	Poorly absorbed	<25%	Primarily to extracellular fluids and vascularized tissues, fetus, ascitic, synovial, and amniotic fluid; minimally into CSF	None	Renal
Streptomycin	Poorly absorbed	35%	Same as gentamicin	10%–30% at unknown site	Renal
β-LACTAMS					
Penicillin G	Erratic, 15%–80% Not available in oral formulation	60%–65%	Penetrates most tissues, fetus, and amniotic fluid; poorly into CSF[b]	Hepatic <30%	Renal
Penicillin V	60%	80%	Penetrates most tissues; poorly into CSF, not used to treat meningitis	Same as penicillin G with additional gut inactivation (metabolized) of 35%–70% of an oral dose	Same as penicillin
PENICILLINASE-RESISTANT PENICILLINS					
Dicloxacillin	35%–76% Give on empty stomach	98%	Penetrates most tissues, fetus, and amniotic fluid; poorly into CSF	Hepatic 10%	Renal
Oxacillin	No oral form available	94%	Penetrates most tissues, fetus, and amniotic fluid; poorly into CSF[b]	Hepatic ~50%	Renal
Nafcillin	Not given orally	90%	Penetrates most tissues, fetus, and amniotic fluid; poorly into CSF[b]	Hepatic 60%	Biliary (wi enterohep recirculati renal 10%–30%
AMINOPENICILLINS					
Amoxicillin	85%	20%	Penetrates most tissues, fetus, and amniotic fluid;	Hepatic 10%	Renal

			poorly into CSF[b]		
Ampicillin	50%	22% 10% in neonates	Penetrates most tissues, fetus, and amniotic fluid; poorly into CSF[b]	Hepatic 10%	Renal
EXTENDED-SPECTRUM PENICILLINS					
Ticarcillin	Not administered orally	45%	Penetrates most tissues, fetus, and amniotic fluid; poorly into CSF[b]	Hepatic 10%	Renal
Piperacillin	Not administered orally	15%–20%	Penetrates most tissues, fetus, and amniotic fluid; poorly into CSF[b]	Hepatic minimal	Renal; bili <20%
BETA-LACTAMASE INHIBITORS					
Avibactam (ceftazidime kinetics are unaffected by avibactam)	Not administered orally	8%	Penetrates abdomen, kidney, muscle; CSF penetration similar to ceftazidime	None	Renal 85% by filtratio and secreti
Clavulanate (amoxicillin pharmacokinetics not affected by clavulanate)	Well absorbed	25%	Penetrates most tissues, fetus, and amniotic fluid; poorly into CSF	Hepatic extensive	Renal 25% 40%
Sulbactam (ampicillin pharmacokinetics not affected by sulbactam)	Not given orally	38%	Penetrates most tissues, fetus, and amniotic fluid; poorly into CSF[b]	Hepatic 10%	Renal
Tazobactam (piperacillin kinetics are unaffected by tazobactam)	Not administered orally	20%–23%	Penetrates most tissues, fetus, and amniotic fluid; poorly into CSF[b]	Hepatic minimal	Renal
CEPHALOSPORINS					
First-Generation					
Cefadroxil	Well absorbed	20%	Penetrates most tissues, fetus, and amniotic fluid; minimally into CSF	None	Renal (slo excretion r than cephalexin
Cefazolin	Not administered orally	80%	Penetrates most tissues, fetus, and	None	Renal

			amniotic fluid; minimally into CSF		
Cephalexin	Well absorbed; ↓ with food	6%	Penetrates most tissues, fetus, and amniotic fluid; minimally into CSF	None	Renal; som biliary
Cephradine	Well absorbed; ↓ with food	10%	Penetrates most tissues, fetus, and amniotic fluid; minimally into CSF	None	Renal; som biliary
Second-Generation					
Cefaclor	Well absorbed	25%	Penetrates most tissues; unknown fetal, amniotic, and CSF distribution	Unknown	Renal (nonrenal: eliminatio unknown in renal failure)
Cefprozil	95%	36%	Penetrates middle-ear fluids and tonsillar, adenoidal, skin, and soft tissues well; unknown fetal, amniotic and CSF distribution	Unknown	Renal; nonrenal 3
Cefuroxime	37% (as axetil); ↑ to 52% when given with food	50%	Penetrates most tissues, fetus, and amniotic fluid; minimally into CSF	None	Renal
Cefoxitin	Not administered orally	75%	Penetrates most tissues, fetus, and amniotic fluid; minimally into CSF[a]	Hepatic minimal	Renal
Third-Generation					
Cefdinir	16%–21% cap; 25% suspension	60%–70%	Penetrates most tissues; unknown fetal, amniotic and CSF distribution	None	Renal
Cefixime	40%–50%	65%–70%	Small distribution volume, penetrates skin, amniotic fluid, poorly to	None	Renal, bilia

			CSF[b]		
Cefoperazone	Not administered orally	90%	Penetrates most tissues, fetus, and amniotic fluid; minimally into CSF[a]	Hepatic <20%	Biliary, rer 20%–30%
Cefotaxime	Not administered orally	35%–40%	Penetrates most tissues, fetus, and amniotic fluid; adequately into CSF[b]	Hepatic	Renal
Cefpodoxime	50%	20%–30%	Penetrates most tissues, unknown fetal, amniotic, and CSF distribution	None	Renal
Ceftazidime	Not administered orally	<10%	Penetrates most tissues, fetus, and amniotic fluid; adequately into CSF[b]	None	Renal
Ceftibuten	>90%	65%–77%	Penetrates most tissues, unknown fetal, amniotic, and CSF distribution	Hepatic minimal	Renal
Ceftriaxone	Not administered orally	95%	Penetrates most tissues, fetus, and amniotic fluid; adequately into CSF[b]	None	Renal; bilia
Fourth-Generation					
Cefepime	Not given orally	20%	Penetrates most tissues, fetus, and amniotic fluid; adequately into CSF[b]	Hepatic minimal	Renal
Ceftolozane	Not given orally	20%	Distribution volume similar to ECV Penetrates lung	None	Renal
CEPHALOSPORINS WITH ANTI-MRSA ACTIVITY					
Ceftaroline	Not administered orally	15%–30%	Distribution volume similar to ECV Penetrates lung tissue, minimal into CSF	Hepatic, minimal (<20%) to inactive metabolite	Renal 80%-90% a unchangec drug, minimal fe (5%)
OTHER B-LACTAMS MONOBACTAMS					

Aztreonam	Not administered orally	50%–70%	Penetrates most tissues, fetus, and amniotic fluid; minimally into CSF[b]	Minimal hydrolysis at unknown site	Renal; bilia minor
CARBAPENEMS					
Meropenem	Not administered orally	Minimal	Penetrates most tissues, CSF[b], fetus, and amniotic fluid.,	Renal, serum, hepatic 20%–25%	Renal; bilia minor
Imipenem (I) + cilastatin (C)	Not administered orally	20% (I) 40% (C)	Penetrates most tissues, fetus, and amniotic fluid; adequately into CSF[b] but relatively contraindicated for meningitis	Renal, serum, hepatic 20%–25%	Renal; bilia minor
Doripenem	Not given orally	8%	Widely distributed, penetrates most body tissues, low to CSF[b]; unknown fetal, amniotic	Renal 18%	Renal, minimal fe
Ertapenem	Not given orally	95%	Penetrates interstitial fluids; unknown fetal, amniotic, or CSF	Renal 20%, hepatic minor	Renal; bilia
CHLORAMPHENICOL SUCCINATE (INJECTION)	PO forms (base and palmitate salt) not available	~50%	Widely distributed including fetal, amniotic, and CSF	Hepatic	Renal (as succinate s and glucuronic metabolite biliary minimal
FLUOROQUINOLONES					
Ciprofloxacin	60%–80%; >90% in adolescents with CF	20%–40%	Penetrates most tissues, fetus, amniotic fluid; minimally into CSF[b]	Hepatic <20%	Renal, fece
Gatifloxacin	96%	20%	Penetrates most tissues including CSF; fetal, amniotic unknown	Minimal	Renal
Levofloxacin	99%	24%–38%	Widely distributed, penetrates most tissues, fetus, amniotic	Minimal	Renal

			fluid, CSF		
Moxifloxacin	90%	50%	Widely distributed penetrates most tissues, CSF, amniotic fluid; poorly to kidney and urine due to metabolism.	Hepatic	Fecal and renal as active drug and metabolite
GLYCOLIPOPEPTIDES					
Dalbavancin	Not given orally	93%	Distribution volume similar to ECV, penetrates skin, bone and joint tissue	Minimal	Renal, feca
Oritavancin	Not given orally	85%	Widely distributed, high lung penetration, weak skin penetration	None known	Renal, feca
Telavancin	Not given orally	90%	Small distribution volume; penetrates skin and lung	Minimal	Renal
KETOLIDES					
Telithromycin	57%	60%–70%	Widely distributed; fetal, amniotic fluid and CSF unknown	Hepatic	Renal, bilia
LINCOSAMIDES					
Clindamycin	90%	94%	Penetrates most tissues, fetus, amniotic fluid; minimally into uninflamed CSF, but adequately into inflamed CSF or brain abscess	Hepatic	Biliary; ren minor
LIPOPEPTIDES					
Daptomycin	Not given orally	~90%	Small distribution volume, penetrates skin, adipose and bone well; fetal, amniotic, and CSF penetration unknown	Minimal	Renal 80% Fecal 5%
MACROLIDES AND AZALIDES					

Azithromycin	37%	20%–50%	Widely distributed including fetus, amniotic fluid; minimally into CSF[b]	Hepatic	Biliary; rer minimal
Clarithromycin	50%–55%	60%–70%	Penetrates most tissues, fetus; CSF penetration unknown	Hepatic	Renal 40%- 50% (as dr and active metabolite
Erythromycin	Poor, 25%–65% depending on salt and form	80%–90%	Penetrates most tissues, fetus, amniotic fluid; minimally into CSF[b]	Hepatic	Biliary, rer minimal
METRONIDAZOLE	100%	<20%	Widely distributed, including fetus, amniotic fluid, CSF	Hepatic	Renal; bilia minor
NITROFURANTOIN	Well absorbed	90%	Mainly urinary tract, prostate, and placenta	Tissues	Renal, bilia
OXAZOLIDINONES					
Linezolid	100%	31%	Penetrates well to most tissues, including CSF; fetus, amniotic fluid unknown	Hepatic	Renal
POLYMYXINS					
Colistimethate (injection)	Not administered orally	Minimal	Penetrates most tissues, fetus and amniotic fluid; minimal to pleural or joint cavities or to CSF	Tissue minor and slow	Renal
RIFAMYCINS					
Rifampin	90%–95%	60%–90%	Widely distributed including fetus, amniotic fluid; minimally into CSF[b]	Hepatic	Biliary, rer
Rifaximin	Poorly absorbed	N/A	Minimal systemic distribution due to poor oral bioavailability, but high intraluminal GI concentrations	Hepatic minimal	Feces absorption
STREPTOGRAMINS					

Quinupristin-dalfopristin	Not administered orally	55%–78% (Q) 11%–26% (D)	Penetrates most tissues; minimally into CSF; fetus, amniotic fluid unknown	Hepatic, conversion to several active metabolites	Biliary; re ~15%
SULFONAMIDES AND TRIMETHOPRIM					
Sulfadiazine	100%	20%	Widely distributed, including fetus, amniotic fluid, CSF	Hepatic wide individual variation	Renal (free and conjugate forms)
Sulfamethoxazole	100%	65%	Widely distributed, including fetus, amniotic fluid, CSF	Hepatic wide individual variation	Renal (free and conjugate forms)
Sulfisoxazole	100%	85%	Widely distributed, including fetus, amniotic fluid, CSF	Hepatic wide individual variation	Renal (free and conjugate forms)
Trimethoprim	100%	~45%	Widely distributed, including fetus, amniotic fluid, CSF	Hepatic <20%	Renal
TETRACYCLINES AND GLYCYLCYCLINES					
Doxycycline	90%–100%	82%	Widely distributed including fetus, amniotic fluid; minimally into CSF[b]	Hepatic	Renal, bilia
Minocycline	90%–100%	76%	Widely distributed including fetus, amniotic fluid; minimally into CSF[b]	Hepatic minimal	Biliary, re
Tetracycline (T), demeclocycline (D)	75%–80%; decreases significantly with food	65% (T) 41%–91% (D)	Widely distributed including fetus, amniotic fluid; minimally into CSF[b]	Hepatic minimal	Renal, bilia
Tigecycline	Not administered orally	70%–90%	Widely distributed; fetal, amniotic fluid and CSF unknown	Hepatic 5%–20%	Biliary, re
GLYCOPEPTIDES					
Vancomycin	Negligible	30%	Penetrates most tissues, fetus, amniotic fluid; adequately but erratically into	None	Renal; bilia minimal

			CSF[b]		

[a] Values listed are the means or medians reported in PK studies and/or product labeling. Actual values in individual patients may differ due to interindividual variability and the effect of certain disease states. Agents with both minimal metabolism and renal excretion will have a prolonged half-life in a patient with renal impairment. See also Chapter 291.

[b] Concentration of drug in CSF significantly increased with inflamed meninges. See text.

CF, cystic fibrosis; CSF, cerebrospinal fluid; ECV, extracellular volume; GI, gastrointestinal; GU, genitourinary; IV, intravenous; PO, *orally*.

TABLE 292.2

Spectrum of Activity of Antimicrobial Agents by Microbial Site of Activity and Antimicrobial Drug Class

I. CELL WALL–ACTIVE AGENTS

A. ANTIBIOTIC CLASS: TRANSPEPTIDASE INHIBITORS

	β-Lactam Antibiotics	Spectrum of Activity[a]
PENICILLINS		
Natural penicillins	Penicillin G Penicillin V Benzathine penicillin G Procaine penicillin G Benzathine-procaine penicillin G combinations	**Gram-positive** Streptococci Groups A, B, C, G, F Viridans group streptococci *Streptococcus pneumoniae* *Enterococcus faecalis*[b] *Enterococcus faecium*[b] *Actinomyces*
		Bacillus anthracis
		Listeria monocytogenes
		Gram-negative
		Eikenella corrodens
		Neisseria meningitidis
		Neisseria gonorrhoeae
		Pasteurella multocida
		Borrelia burgdorferi
		Spirillum minus
		Streptobacillus moniliformis
		Treponema pallidum
		Leptospira spp.
		Anaerobes
		Bacteroides and *Prevotella* spp. (non-β-lactamase–producing strains)
		Fusobacterium spp.
		Veillonella spp.
		Clostridium spp.
		Eubacterium spp.
		Peptococcus spp.
		Peptostreptococcus spp.
		Propionibacterium spp.
Penicillinase-stable penicillins	Methicillin Oxacillin Nafcillin Cloxacillin Dicloxacillin	**Gram-positive** Streptococci (as above for penicillins) *Staphylococcus aureus* (except MRSA)
Aminopenicillins	Ampicillin	**Gram-positive**
	Amoxicillin	Streptococci (as above for penicillins)
		Enterococcus faecalis[b]
		Enterococcus faecium[b]
		Listeria monocytogenes

		Gram-negative
		Escherichia coli
		Haemophilus influenzae
		Neisseria meningitidis
		Anaerobes
		For ampicillin: as above for penicillins
	Amoxicillin-clavulanate	Adds activity to amoxicillin:
		Staphylococcus aureus (except MRSA)
		Haemophilus influenzae, β-lactamase–producing strains
		Anaerobes
		As above for penicillins, but now includes:
		Bacteroides and *Prevotella* spp., β-lactamase–producing strains
	Ampicillin-sulbactam	Adds activity to ampicillin:
		Staphylococcus aureus (except MRSA)
		Escherichia coli, β-lactamase–producing strains
		Klebsiella spp.
		Proteus mirabilis
		Proteus vulgaris
		Providencia rettgeri
		Providencia stuartii
		Morganella morganii
		Anaerobes
		As above for penicillins, but now includes:
		Bacteroides and *Prevotella* spp. (β-lactamase–producing strains)
Extended-spectrum pencillins	Carbenicillin Ticarcillin Piperacillin	**Gram-positive**
		Streptococci (as above for penicillins)
		Gram-negative
		Escherichia coli
		Haemophilus influenzae
		Proteus mirabilis
		Proteus vulgaris
		Morganella morganii
		Pseudomonas aeruginosa
		Providencia rettgeri
		Enterobacter species
		Anaerobes
		Bacteroides and *Prevotella* spp. (non-β-lactamase –producing strains)
		Fusobacterium spp.
		Veillonella spp.
		Clostridium spp.
		Eubacterium spp.
		Peptococcus spp.
		Peptostreptococcus spp.
	Ticarcillin-clavulanate	Adds β-lactamase–producing strains of:
	Piperacillin-tazobactam	*Staphylococcus aureus* (except MRSA)
		Escherichia coli
		Haemophilus influenzae
		Klebsiella spp.
		Serratia marcescens
		Citrobacter spp.

		Enterobacter spp.
		Anaerobes
		Bacteroides and *Prevotella* spp. (including β-lactamase –producing strains)
		Fusobacterium spp.
		Veillonella spp.
		Clostridium spp.
		Eubacterium spp.
		Peptococcus spp.
		Peptostreptococcus spp.
CEPHALOSPORINS		
First-generation	Cephalothin Cephapirin Cefazolin Cephalexin Cephradine Cefadroxil	**Gram-positive** Streptococci Groups A, B, C, G, F Viridans group streptococci *Streptococcus pneumoniae*
		Staphylococcus aureus (except MRSA)
		Gram-negative
		Escherichia coli
		Proteus mirabilis
Second-generation	Cefamandole Cefuroxime Cefonicid Ceforanide Cefaclor Cefoxitin Cefotetan	**Gram-positive** Streptococci Groups A, B, C, G, F Viridans group streptococci *Streptococcus pneumoniae* *Staphylococcus aureus* (except MRSA)
		Gram-negative
		Escherichia coli
		Haemophilus influenzae (including β-lactamase –producing strains)
		Klebsiella spp.
		*Moraxella catarrhali*s
		Neisseria gonorrhoeae
		Neisseria meningitidis
		Proteus mirabilis
		Providencia rettgeri
		Salmonella spp.
		Shigella spp.
		Anaerobes
		Bacteroides and *Prevotella* spp. (non-β-lactamase –producing strains, except for cefoxitin and, to a lesser extent, cefotetan)
		Fusobacterium spp.
		Veillonella spp.
		Eubacterium spp.
		Peptococcus spp.
		Peptostreptococcus spp.
Third-generation	Cefotaxime Ceftriaxone Ceftazidime Cefoperazone Ceftizoxime Cefixime Cefpodoxime Ceftibuten Cefdinir	**Gram-positive** Streptococci Groups A, B, C, G, F Viridans group streptococci *Streptococcus pneumoniae* *Staphylococcus aureus* (except MRSA) **Gram-negative**
		Citrobacter spp.
		Enterobacter spp.

		Escherichia coli
		Haemophilus influenzae (including β-lactamase –producing strains)
		Klebsiella spp.
		Morganella morganii
		Neisseria gonorrhoeae (including β-lactamase–producing strains)
		Neisseria meningitidis
		Proteus mirabilis
		Proteus vulgaris
		Providencia rettgeri
		Providencia stuartii
		Serratia marcescens
		For ceftazidime and cefoperazone:
		Pseudomonas aeruginosa
		Anaerobes
		Bacteroides and *Prevotella* spp. (non-β-lactamase –producing strains)
		Fusobacterium spp.
		Eubacterium spp.
		Peptococcus spp.
	Ceftazidime-avibactam	Adds activity to ceftazidime to include many ESBL producing *E. coli* and *Klebsiella,* and adds activity against *Klebsiella* that produce *K. pneumoniae* carbapenemases
	Ceftolozane-tazobactam	Adds activity to ceftolozane (enhanced *Pseudomonas* activity beyond ceftazidime) to include many ESBL producing *E. coli* and *Klebsiella*
Fourth-generation	Cefepime	**Gram-positive**
		Streptococci
		Groups A, B, C, G, F
		Viridans group streptococci
		Streptococcus pneumoniae
		Staphylococcus aureus (except MRSA)
		Gram-negative
		As above for third-generation cephalosporins, but including *Pseudomonas aeruginosa*)
		Anaerobes
		Bacteroides and *Prevotella* spp. (non-β-lactamase –producing strains)
		Fusobacterium spp.
		Veillonella spp.
		Eubacterium spp.
		Peptococcus spp.
Advanced-generation	Ceftaroline	As above for third-generation cephalosporins, but also includes MRSA strains of *Staphylococcus aureus*
CARBAPENEMS	Imipenem (with cilastatin)	**Gram-positive**
	Meropenem	Streptococci
	Ertapenem	Groups A, B, C, D, G, F
	Doripenem	Viridans group streptococci
		Streptococcus pneumoniae
		Enterococcus faecalis
		Staphylococcus aureus (except MRSA)
		Gram-negative
		Acinetobacter spp.
		Citrobacter spp.

		Enterobacter spp.
		Escherichia coli (including ESBL-producing strains)
		Gardnerella vaginalis
		Haemophilus influenzae
		Klebsiella spp. (including ESBL-producing strains)
		Morganella morganii
		Proteus vulgaris
		Providencia rettgeri
		Pseudomonas aeruginosa (except ertapenem)
		Serratia spp.
		Anaerobes
		Bifidobacterium spp.
		Clostridium spp.
		Eubacterium spp.
		Peptococcus spp.
		Peptostreptococcus spp.
		Propionibacterium spp.
		Bacteroides and *Prevotella* spp. (including β-lactamase –producing strains)
		Fusobacterium spp.
MONOBACTAMS	Aztreonam	**Gram-negative**
		Citrobacter spp.
		Enterobacter spp.
		Escherichia coli
		Haemophilus influenzae (including β-lactamase –producing strains)
		Klebsiella spp.
		Proteus mirabilis
		Pseudomonas aeruginosa
		Serratia spp.
B. ANTIBIOTIC CLASS: TRANSGLYCOSYLASE INHIBITORS		
		Spectrum of Activity[a]
GLYCOPEPTIDES	Vancomycin, telavancin, dalbavancin, oritavancin	**Gram-positive** Streptococci Groups A, B, C, G, F Viridans group streptococci
		Streptococcus pneumoniae
		Enterococcus faecalis[b]
		Enterococcus faecium[b]
		Staphylococcus aureus (including MRSA, but not vancomycin-intermediate or vancomycin-resistant strains)
		Staphylococcus epidermidis
		Actinomyces spp.
		Lactobacillus spp.
		Listeria monocytogenes
		Anaerobes
		Clostridium difficile

II. CELL MEMBRANE ACTIVE AGENTS		
A. ANTIBIOTIC CLASS: LIPOPEPTIDES		
		Spectrum of Activity[a]
	Daptomycin	*Staphylococcus aureus* (including methicillin-resistant and vancomycin-resistant strains)
		Enterococcus faecalis (vancomycin-susceptible and vancomycin-resistant strains)
		Enterococcus faecium (vancomycin-susceptible and vancomycin-resistant strains)

		Streptococci
		Groups A, B
		Viridans group streptococci
B. ANTIBIOTIC CLASS: POLYMYXINS		
	Colistin	*Enterobacter aerogenes*
		Escherichia coli
		Klebsiella pneumoniae
		Pseudomonas aeruginosa
		Actinobacter spp.
		Citrobacter spp.
		Haemophilus spp.
		Salmonella spp.
		Shigella spp.

III. RIBOSOME-ACTIVE AGENTS		
A. ANTIBIOTIC CLASS: MACROLIDES		
MACROLIDES	Erythromycin	**Gram-positive**
		Corynebacterium diphtheriae
		Corynebacterium minutissimum
		Listeria monocytogenes
		Staphylococcus aureus
		Streptococcus pneumoniae
		Streptococcus pyogenes
		Gram-negative
		Bordetella pertussis
		Legionella pneumophila
		Neisseria gonorrhoeae
		Other pathogens
		Chlamydia trachomatis
		Entamoeba histolytica
		Mycoplasma pneumoniae
		Treponema pallidum
		Ureaplasma urealyticum
	Clarithromycin	**Gram-positive**
		Staphylococcus aureus
		Streptococcus pneumoniae
		Streptococcus pyogenes
		Gram-negative
		Haemophilus influenzae
		Moraxella catarrhalis
		Helicobacter pylori
		Other pathogens
		Mycoplasma pneumoniae
		Chlamydophila pneumoniae
		Mycobacterium avium complex
AZALIDES	Azithromycin	**Gram-positive**
		Staphylococcus aureus
		Streptococci
		Groups A, B C, F, G
		Viridans group streptococci
		Streptococcus pneumoniae
		Bordetella pertussis
		Gram-negative
		Haemophilus influenzae
		Haemophilus ducreyi

		Moraxella catarrhalis
		Neisseria gonorrhoeae
		Other pathogens
		Chlamydophila pneumoniae
		Chlamydia trachomatis
		Legionella pneumophila
		Mycoplasma hominis
		Mycoplasma pneumoniae
		Ureaplasma urealyticum
KETOLIDES	Telithromycin	**Gram-positive**
		Staphylococcus aureus
		Streptococci
		Groups A, C, and G
		Viridans group streptococci
		Gram-negative
		Haemophilus influenzae
		Moraxella catarrhalis
		Other pathogens
		Bordetella pertussis
		Mycoplasma pneumoniae
		Legionella pneumophila
		Chlamydophila pneumoniae
B. ANTIBIOTIC CLASS: TETRACYCLINES		
TETRACYCLINES	Tetracycline Minocycline Doxycycline	**Gram-positive** *Actinomyces* spp. **Gram-negative** *Vibrio cholerae*
		Brucella spp.
		Campylobacter spp.
		Francisella tularensis
		Listeria monocytogenes
		Yersinia pestis
		Neisseria meningitidis
		Neisseria gonorrhoeae
		Other pathogens
		Borrelia recurrentis
		Chlamydophila psittaci
		Chlamydia trachomatis
		Mycoplasma pneumoniae
		Ureaplasma
		Treponema pallidum
		Entamoeba species
GLYCYLCYCLINES	Tigecycline	**Gram-positive**
		Streptococci
		Groups A, B
		Viridans group streptococci
		Streptococcus pneumoniae
		Enterococcus faecalis
		Enterococcus faecium
		Staphylococcus aureus
		Listeria monocytogenes
		Clostridium perfringens
		Peptostreptococcus spp.
		Gram-negative
		Acinetobacter baumannii
		Aeromonas hydrophila

		Citrobacter freundii
		Citrobacter koseri
		Enterobacter cloacae
		Enterobacter aerogenes
		Escherichia coli
		Klebsiella oxytoca
		Klebsiella pneumoniae
		Pasteurella multocida
		Serratia marcescens
		Stenotrophomonas maltophilia
		Bacteroides spp.
		Other pathogens
		Chlamydia trachomatis
		Mycoplasma pneumoniae
		Ureaplasma
		Mycobacterium abscessus
		Mycobacterium chelonae
		Mycobacterium fortuitum
C. ANTIBIOTIC CLASS: LINCOSAMIDES		
LINCOSAMIDES	Clindamycin	**Gram-positive**
		Streptococci
		Groups A, B
		Streptococcus pneumoniae
		Staphylococcus aureus
		Anaerobes
		Bacteroides fragilis
		Prevotella melaninogenica
		Fusobacterium spp.
		Peptococcus spp.
		Peptostreptococcus spp.
		Actinomyces spp.
		Clostridium perfringens
		Propionibacterium spp.
D. ANTIBIOTIC CLASS: AMINOGLYCOSIDES		
AMINOGLYCOSIDES	Streptomycin	**Gram-negative**
		Brucella spp.
		Francisella spp.
		Mycobacterium tuberculosis
	Gentamicin Netilmicin Tobramycin Amikacin	**Gram-positive** *Staphylococcus aureus* **Gram-negative** *Escherichia coli* *Klebsiella* spp.
		Enterobacter spp.
		Serratia spp.
		Citrobacter spp.
		Morganella morganii
		Acinetobacter spp.
		Providencia spp.
		Proteus mirabilis
		Proteus vulgaris
		Pseudomonas aeruginosa
	Paromomycin	*Entamoeba histolytica*
		Dientamoeba fragilis
		Cryptosporidium spp.
E. ANTIBIOTIC CLASS: OXAZOLIDINONES		

OXAZOLIDINONES	Linezolid, tedizolid	**Gram-positive**
		Streptococci
		Groups A, B
		Viridans group streptococci
		Streptococcus pneumoniae
		Staphylococcus aureus
		Enterococcus faecium
		Enterococcus faecalis
F. ANTIBIOTIC CLASS: STREPTOGRAMINS		
STREPTOGRAMINS	Quinupristin/dalfopristin	**Gram-positive**
		Streptococci
		Groups A, B
		Staphylococcus aureus
		Enterococcus faecium

IV. NUCLEIC ACID–ACTIVE ANTIBIOTICS		
A. ANTIBIOTIC CLASS: RIFAMYCINS		
RIFAMYCINS	Rifampin	**Gram-positive**
		Staphylococcus aureus
		Gram-negative
		Neisseria meningitidis
		Haemophilus influenzae
		Other
		Mycobacterium tuberculosis
		Mycobacterium avium complex
	Rifabutin	*Mycobacterium tuberculosis*
	Rifapentine	*Mycobacterium avium* complex
	Rifaximin	Susceptible at concentrations achieved within the gastrointestinal lumen:
		Campylobacter
		Escherichia coli
		Salmonella spp.
		Shigella spp.
		Vibrio spp.
		Yersinia spp.
B. ANTIBIOTIC CLASS: QUINOLONES		
QUINOLONES	Nalidixic acid	**Gram-negative**
		Escherichia coli
		Enterobacter spp.
		Morganella morganii
		Proteus mirabilis
		Proteus vulgaris
		Providencia rettgeri
FLUOROQUINOLONES	Ciprofloxacin	**Gram-positive**
		Streptococcus pyogenes
		Streptococcus pneumoniae
		Staphylococcus aureus
		Enterococcus faecalis
		Bacillus anthracis
		Gram-negative
		Aeromonas spp.
		Acinetobacter spp.
		Escherichia coli
		Klebsiella pneumoniae

		Enterobacter cloacae
		Citrobacter diversus
		Citrobacter freundii
		Campylobacter jejuni
		Proteus mirabilis
		Proteus vulgaris
		Providencia rettgeri
		Providencia stuartii
		Serratia marcescens
		Pseudomonas aeruginosa
		Morganella morganii
		Salmonella spp.
		Shigella spp.
		Haemophilus influenzae
		Haemophilus parainfluenzae
		Moraxella catarrhalis
		Neisseria gonorrhoeae[b]
		Pasteurella multocida
		Vibrio spp.
		Yersinia enterocolitica
		Other pathogens
		Legionella pneumophila
	Levofloxacin Gemifloxacin Moxifloxacin	**Gram-positive** Streptococci Group A Viridans group streptococci
		Streptococcus pneumoniae
		Enterococcus faecalis
		Staphylococcus aureus
		Actinomyces spp.
		Bacillus anthracis
		Listeria monocytogenes
		Gram-negative
		Acinetobacter spp.
		Escherichia coli
		Enterobacter spp.
		Klebsiella spp.
		Proteus spp.
		Providencia spp.
		Serratia marcescens
		Citrobacter spp.
		Morganella morganii
		Pseudomonas aeruginosa
		Haemophilus influenzae
		Moraxella catarrhalis
		Anaerobes
		Clostridium perfringens
		Other pathogens
		Legionella pneumophila
		Mycoplasma pneumoniae
		Chlamydophila pneumoniae
C. ANTIBIOTIC CLASS: NITROIMADAZOLES		
NITROIMADAZOLES	Metronidazole	**Anaerobes**
		Clostridium spp.
		Eubacterium spp.
		Peptococcus spp.

		Peptostreptococcus spp.
		Bacteroides fragilis
		Fusobacterium spp.
D. ANTIBIOTIC CLASS: SULFONAMIDES		
SULFONAMIDES	Sulfisoxazole Sulfamethoxazole	
SULFA IN COMBINATION WITH ANOTHER ANTIMICROBIAL AGENT	Sulfamethoxazole plus trimethoprim	**Gram-positive** *Streptococcus pneumoniae*[b] **Gram-negative**
		Escherichia coli
		Klebsiella spp.
		Enterobacter spp.
		Morganella morganii
		Proteus mirabilis
		Proteus vulgaris
		Shigella spp.
		Haemophilus influenzae
		Other pathogens
		Pneumocystis jirovecii
	Sulfadiazine plus pyramethamine	*Toxoplasma gondii* *Plasmodium* spp.

[a] A majority of strains of the listed bacteria are susceptible; however, some organisms within the group may be less susceptible or resistant to one or more agents listed. Susceptibility pattern for each pathogen and antibiotic may be available to physicians through local health care institutions.

[b] Important exceptions exist.

ESBL, extended-spectrum β-lactamases; MRSA, methicillin-resistant *Staphylococcus aureus.*

Cell Wall–Active Agents

The synthesis of the bacterial cell wall is remarkably complicated and still is not understood fully.[1–3] Several steps are involved in cell wall creation, from the synthesis of precursors within the bacterial cytoplasm to the intricate construction of a lattice-like structure around the organism that maintains cell shape and osmotic integrity. Gram-negative cell walls consist of inner (plasma) and outer membranes and are more complicated than those of gram-positive organisms that contain a single membrane. Many steps in cell wall synthesis have been exploited as targets of currently available antimicrobial agents, and others provide potential targets for ongoing anti-infective research (Fig. 292.1). Our understanding of mechanisms of cell death following interruption of cell wall synthesis has increased to recognize both mechanisms of direct cell wall damage and initiation of metabolic pathways for programmed cell death.[3]

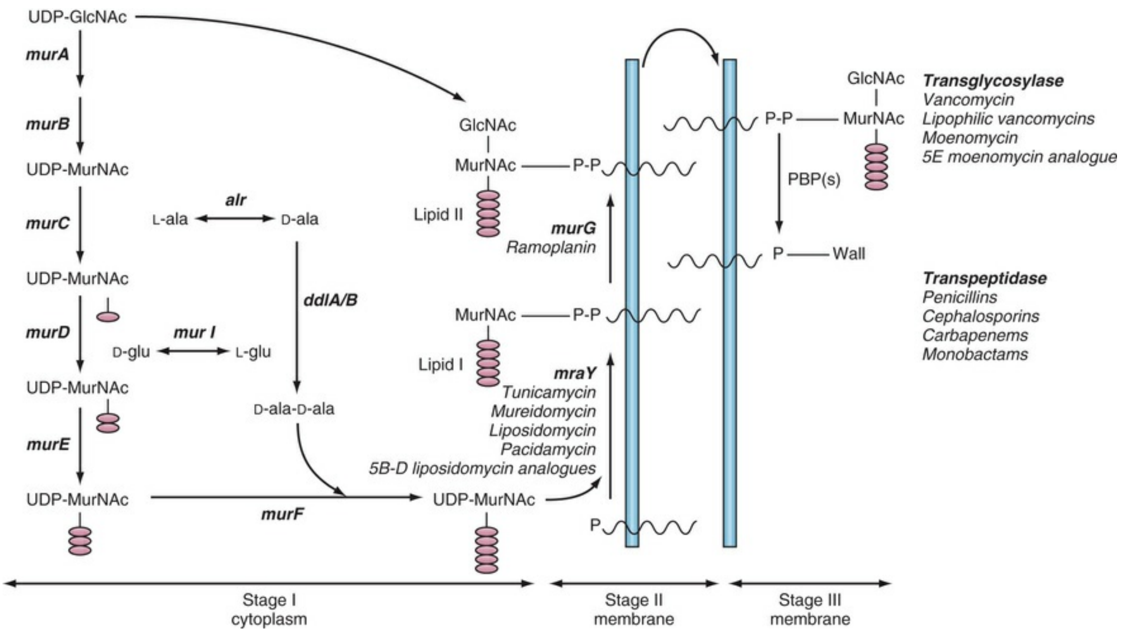

FIGURE 292.1 The peptidoglycan synthesis pathway in cell wall formation. D-ala, D-alanine; GlcNAc, *N*-acetylglucosamine; L-ala, L-alanine; MurNAc, *N*-acetylmuramic acid; PBP(s), penicillin-binding proteins (transpeptidase); UDP, uridine diphosphate. (Redrawn with modification from Wong VK, Pompliano DL. Peptidoglycan biosynthesis:

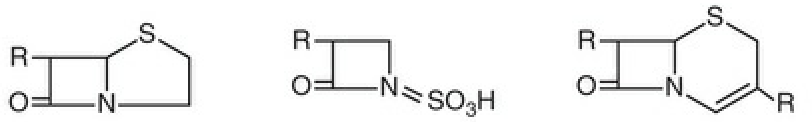
unexploited targets within a familiar pathway. In: Rosen BP, Mobashery S [eds]. Resolving the Antibiotic Paradox. New York, Kluwer Academic/Plenum Publishers, 1998, pp. 197–217.)

The saccharide precursors of cell walls, *N*-acetylmuramic acid (MurNAc), and *N*-acetylglucosamine (GlcNAc) are modified enzymatically by a series of steps, with MurNAc acquiring a side chain consisting of five peptides, incorporating D-alanine, D-alanine as the terminal two amino acids in this chain. This MurNAc pentapeptide is subsequently attached to a GlcNAc saccharide unit, completing the disaccharide pentapeptide building block required for cell wall peptidoglycan formation (see Fig. 292.1). Agents that inhibit these initial steps have been identified in a research setting, and many are currently under investigation as clinically important targets.[4,5] The disaccharide pentapeptide building block subsequently is transferred through the cell membrane to undergo further modification, ultimately to create the peptidoglycan structure either outside the cell membrane (in gram-positive organisms) or between the inner plasma membrane and outer membrane within the cell wall (in gram-negative organisms). Linking of the disaccharide pentapeptide building blocks occurs by transglycosylation and creates repeating disaccharide subunits (GlcNAc-MurNAc-pentapeptide) to produce long glycan chains.[6] Vancomycin and related glycopeptide antibiotics inhibit this step in cell wall synthesis by binding to the terminal D-alanine, D-alanine of the pentapeptide attached to MurNAc and by interfering sterically with the enzymatic function of the transglycosylase.[7]

The mature glycan chains containing the repeating disaccharide units subsequently are linked by connecting the pentapeptides located on the MurNAc units from adjacent glycan chains. In this transpeptidation step, a stable bridge is created between glycan chains to form the two-dimensional peptidoglycan structure.[6] The β-lactam class of antibiotics inhibits the transpeptidase function by binding covalently to the active serine site of the enzyme responsible for linking the two pentapeptide arms from MurNAc units on adjacent glycan strands.[8] The structure of enzymes that are responsible for transglycosylation and transpeptidation varies somewhat between bacteria. Fortunately, the active sites of these enzymes tend to be conserved. An organism often contains several transpeptidases, each responsible for a different cell wall function, including repair, elongation, septation, and cell wall thickening, among others. Some of these enzymes contain both transglycosylation and transpeptidation functions. Historically, these enzymes were identified by penicillin attachment to them and are also known as *penicillin-binding proteins* or (PBPs).

β-Lactam Antibiotics

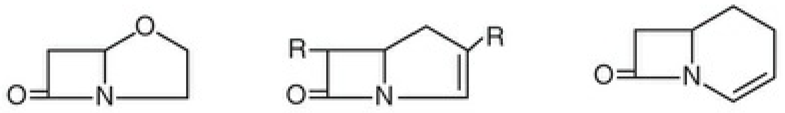
The β-lactam antibiotics all share the capacity to inhibit the transpeptidase cross-linking of peptidoglycan in the final steps of formation of the cell wall. Whereas the β-lactam structure itself is consistent across all antibiotics in this class, the ring to which the lactam moiety is fused is variable, with relatively small differences in the composition of the ring allowing for variable activity against the PBPs of both gram-positive and gram-negative bacteria (Fig. 292.2). The addition of chemical "chains" to the ring structures enhances activity against certain organisms, but simultaneously can decrease activity against others. Differences in the charges of the antibiotic molecule affect the ability of the compound to reach and to bind to its target, particularly for gram-negative pathogens.



Penam (penicillin, ampicillin)

Monobactam

Cephem (ceffriaxone, cefotaxime)



Clavam (clavulanate)

Carbapenem (meropenem)

Carbacephem (loracarbef)

FIGURE 292.2 β-Lactam antibiotic structures.

In general, the β-lactam antibiotics are bactericidal, with the concentrations required for killing being very close to those required for inhibition of growth. The maximal bactericidal effect occurs on rapidly growing bacteria; in stationary phase (or as sessile organisms in biofilms), this class of antibiotics has substantially less bactericidal effect.[9]

Resistance to β-Lactam Antibiotics

Probably just as ancient as the natural antibiotics are natural mechanisms for resistance to them (Fig. 292.3). Resistance to the β-lactam antibiotics occurs primarily in four ways: (1) enzymatic hydrolysis of the β-lactam ring by bacterial β-lactamases, rendering the antibiotic harmless; (2) alterations in the structure of the transpeptidase, so that binding of the antibiotic to the active serine site of the transpeptidase does not occur; (3) efflux pumps that, in gram-negative organisms, quickly and efficiently remove the antibiotics from the periplasmic space before they can bind to the transpeptidases; and (4) alterations in the gram-negative outer membrane proteins that prevent the antibiotic from entering the periplasmic space. Each resistance mechanisms is variably effective and can lead either to profound resistance or merely to slightly increased resistance that has no clinical effect. Unfortunately, some pathogens combine several resistance mechanisms, each creating incremental increases in β-lactam resistance, ultimately leading to the development of an organism that is no longer susceptible to these antibiotics.

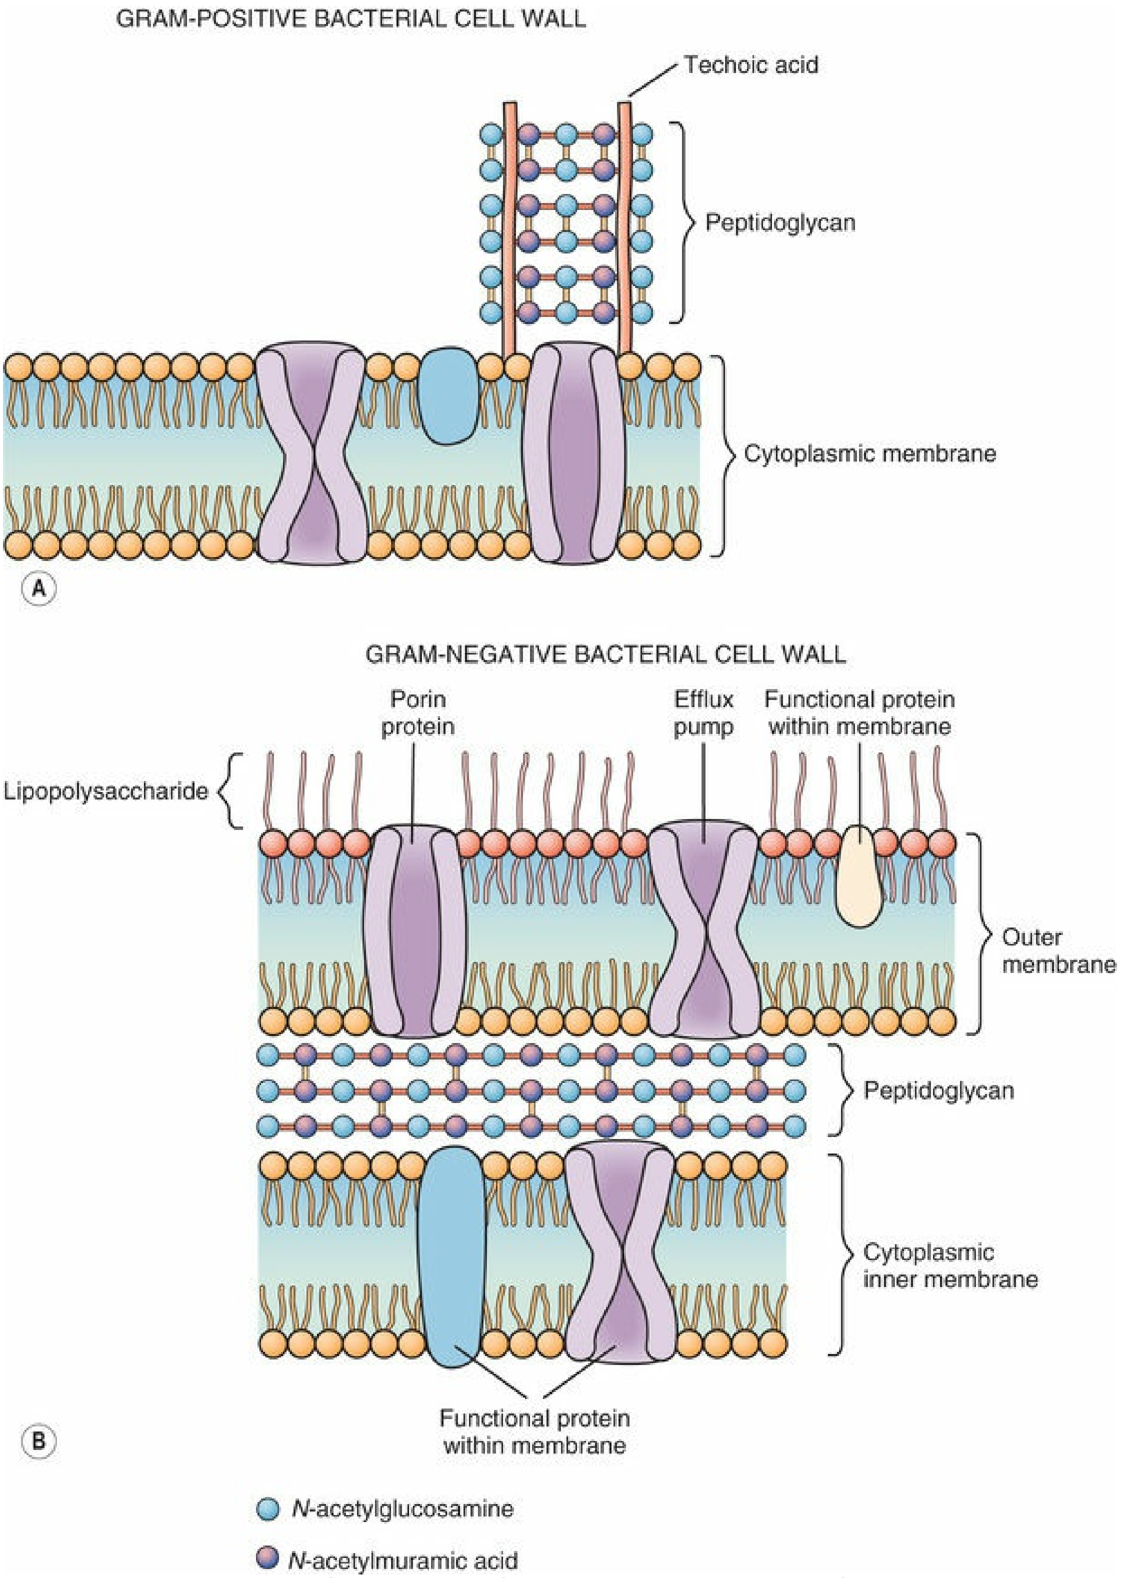


FIGURE 292.3 Structure of bacterial cell walls of gram-positive (A) and gram-negative (B) bacteria.

Chemical modifications of the β-lactam ring and associated drug structure can enhance the intrinsic activity of a drug against bacterial pathogens. Modifications that alter ionic charges on the molecule can allow the new agent (e.g., ampicillin) to enter the gram-negative bacterial periplasmic space, in contrast to an older agent (e.g., penicillin G) that could not. Side chains can create enhanced stability of the antibiotic against one or more of the hundreds of β-lactamases that have been identified, or can enhance binding to bactericidal targets within the organism.[4] Unfortunately, new, more active and broader spectrum β-lactamases are reported with disturbing regularity.[10] Although many different efflux pump systems exist, changes in the structure and charge of the antibiotic can decrease the affinity of the antibiotic for the pump, while hopefully not decreasing its affinity for the target transpeptidase.

Penicillins

The penicillins are the most commonly used antibiotics in pediatrics and can be divided broadly into four different groups: (1) natural penicillins, (2) penicillinase-stable penicillins, (3) aminopenicillins, and (4) extended-spectrum penicillins.

Natural Penicillins

Natural penicillins are the natural products of *Penicillium chrysogenum.* It is likely that both penicillins and penicillin-resistance mechanisms evolved millions of years ago as result of competition for survival between single-cell organisms.[11] Fleming's observations in the 1920s led to the identification of penicillin and the discovery of the mechanism by which *Penicillium* killed other bacteria, paving the way for the modern era of antibacterial therapy. The basic structure of penicillin, 6-aminopenicillanic acid, is characteristic of the lactam ring fused to a larger ring structure to create a penam nucleus that is the basic structure of all penicillins (see Fig. 292.2). Of the natural penicillins, only penicillin G (crystalline penicillin G, benzyl penicillin G) and penicillin V (phenoxymethyl-penicillin) currently are available commercially. Penicillin G is available in both oral and parenteral formulations. For intramuscular injection, penicillin G also is available in repository forms of the drug. Procaine penicillin G and benzathine penicillin G both have much longer serum elimination half-lives as a result of prolonged absorption from the muscle injection site, compared with crystalline penicillin G. However, the peak serum concentrations of the repository forms of penicillin G are a fraction of that achieved with intravenous administration of crystalline penicillin G. Therefore the only settings in which the repository forms of penicillin are effective are those in which the targeted organisms are exquisitely susceptible to penicillin, existing in tissues with good perfusion. Intramuscular procaine penicillin has a half-life of approximately 12 hours and achieves peak serum concentrations of about 2 μg/mL, compared with a half-life of 30 to 50 minutes for crystalline penicillin G and achieved peak serum concentrations of approximately 20 μg/mL. Benzathine penicillin G yields serum concentrations of only about 1.5 μg/mL but can remain above 0.2 μg/mL for ≥3 weeks. Combinations of procaine and benzathine penicillin, either in equal amounts or as a 3 : 1 (benzathine to procaine) mixture, also are available. Because these repository forms of penicillin are used infrequently, extreme caution must be taken never to administer them intravenously, which can be lethal.

In clinical practice, although active against a wide range of bacteria (see Table 292.2), the natural penicillins are used most widely for treatment and prevention of infections caused by streptococci. Pharyngitis, lower respiratory tract infection, skin and skin structure infections, and bloodstream infection (BSI) caused by group A *Streptococcus* (*Streptococcus pyogenes*) are effectively treated with penicillin. The in vitro susceptibility of these organisms has remained unchanged over the past several decades,[12] although the efficacy in the treatment of streptococcal pharyngitis in more recent studies is less than expected, for reasons that are not well understood.[13] Intramuscular injections of benzathine penicillin every 3 to 4 weeks are effective in the prevention of rheumatic fever because of the prolonged tonsillar tissue concentrations of penicillin G.

Empiric penicillin therapy of infections suspected to be caused by *Streptococcus pneumoniae* was not appropriate during the mid-1990s and did not become appropriate until approximately 2010, as a result of widespread decreased susceptibility of pneumococci to penicillin. Certain serotypes of pneumococcus were able to acquire genetic resistance and form stable alterations in the structure of several pneumococcal PBPs, yielding penicillin-nonsusceptible organisms, treatment of which requires use of higher dosages of penicillins or agents from other antibiotic classes. However, if culture results during that era or presently document susceptibility, penicillin still represents highly effective therapy. Fortunately, widespread use of protein-conjugated vaccines against the most antibiotic-resistant and virulent serotypes have had a dramatic impact in decreasing both the number and antibiotic resistance of pneumococcal infections.

Most anaerobes, with the exception of β-lactamase–producing strains of *Bacteroides* spp. and *Prevotella* spp., are highly susceptible to penicillin G. However, because of the common isolation of *Bacteroides fragilis* among the anaerobes present in intra-abdominal infections and *Prevotella melaninogenica* among the organisms causing sinus-related and deep head and neck space infections, including brain abscesses, agents active against β-lactamase –producing anaerobes are preferred to treat infections at these sites.

Penicillin G continues to play a role in the treatment of infections caused by other α- and β-hemolytic streptococci, most of which remain susceptible. For life-threatening infections such as bacterial endocarditis, susceptibility testing should be performed to ensure that the organisms do not exhibit penicillin tolerance, which may decrease treatment success using single-drug therapy at standard dosages.

Penicillin G is effective therapy for less common infections, including diphtheria, naturally occurring anthrax, actinomycosis, leptospirosis, and syphilis.

Penicillinase-Stable Penicillins

The class of semisynthetic penicillins represented by methicillin, oxacillin and nafcillin was created to meet the challenge of the development of penicillin-resistant *Staphylococcus aureus.* The bulky side chains prevent the staphylococcal β-lactamases from binding to and hydrolyzing the lactam ring of the molecule. However, these antibiotics are resistant only to staphylococcal penicillinases, and not to the β-lactamases of gram-negative organisms. These antibiotics are not active against methicillin-resistant *S. aureus* (MRSA) because of the presence of a transpeptidase (PBP2a), which had not been capable of being bound and inactivated by any β-lactam antibiotic until the approval of ceftaroline in 2010.

In clinical practice, these antibiotics are used to treat infections caused by methicillin-susceptible *S. aureus* (MSSA). They are available in both parenteral and oral formulations. With the emergence of community-associated (CA)-MRSA, their longstanding role in the empiric therapy of presumed staphylococcal infections is compromised. For MSSA, however, these semisynthetic penicillins are safe and highly effective.

Aminopenicillins

The aminopenicillin class of semisynthetic penicillins (as represented by ampicillin and amoxicillin) contains an amino substitution in the phenyl acetamido side chain of the penam nucleus, providing a polar charge on the molecule that allows activity against gram-negative pathogens, including *Escherichia coli* and *Haemophilus influenzae* (see Table 292.2). However, aminopenicillins are not stable to staphylococcal penicillinases, or to the hundreds of different β-lactamases elaborated by gram-negative pathogens. Their activity against other gram-positive organisms, such as group A and group B *Streptococcus* spp., is excellent, and activity against most enterococci is equivalent to or better than penicillin G.

As a means of enhancing the activity of the aminopenicillins against β-lactamase–producing pathogens, the concurrent use of a second agent that binds irreversibly to a pathogen's β-lactamase has led to a useful group of drugs. These concurrently used agents, called β-lactamase inhibitors, have little antibiotic activity on their own because they have been selected for avid binding characteristics to specific β-lactamases, rather than to PBPs. However, there is variability in the binding affinity of each β-lactamase inhibitor to the β-lactamases of different organisms. Currently in the United States, clavulanate is paired with amoxicillin in an oral formulation (and a parenteral formulation in other parts of the world), ampicillin is paired with sulbactam, and piperacillin is paired with tazobactam in parenteral preparations (see Table 292.2).

The clinical uses of ampicillin and amoxicillin are extensive. The enhanced activity against *E. coli* and other gram-negative enteric bacilli compared with penicillin G permits ampicillin and amoxicillin to be used for the treatment of some urinary tract infections (UTIs) and gastrointestinal infections. The excellent activity against β-lactamase–negative strains of *H. influenzae* allows ampicillin and amoxicillin to be used in the treatment of upper and lower respiratory tract infections. Ampicillin is one of the most bactericidal agents when used together with gentamicin for susceptible strains of *Enterococcus.* Unfortunately, the development of ampicillin resistance in *E. coli, Shigella, Salmonella,* and *H. influenzae* has limited the usefulness of aminopenicillins against these pathogens.

However, the addition of clavulanate to amoxicillin allows activity against β-lactamase–producing strains of *H. influenzae* and *Moraxella catarrhalis* as well as MSSA. This combination increases the clinical usefulness of amoxicillin in the treatment of community-associated upper and lower respiratory tract infections (e.g., acute otitis media, sinusitis, and pneumonia), in addition to skin and skin structure infections. Clavulanate alone has little effect on ampicillin-resistant *E. coli*. The addition of sulbactam to ampicillin allows activity against many β-lactamase–producing organisms, including staphylococci, many enteric gram-negative bacilli (not *E. coli* typically), and *B. fragilis.* Ampicillin-sulbactam can be used for treatment of complicated pneumonia, skin and skin structure infections, and some intra-abdominal infections, which is not possible with ampicillin alone.

Extended-Spectrum Penicillins

Extended-spectrum semisynthetic penicillins are designed to increase activity against gram-negative pathogens, including *Klebsiella, Enterobacter,* and, for some agents, *Pseudomonas* (see Table 292.2). The two major classes are the carboxypenicillins, represented by ticarcillin and carbenicillin, and the acylureidopenicillins, represented by piperacillin. Although the spectrum of activity of these antibiotics has been enhanced beyond the aminopenicillins, they remain susceptible to hydrolysis by many β-lactamases, including those of MSSA. Similar to the aminopenicillins, activity of these drugs has been enhanced by pairing them with β-lactamase inhibitors, such as ticarcillin-clavulanate and piperacillin-tazobactam.

The clinical uses of these antibiotics reflect their broad activity against gram-negative enteric bacilli and *Pseudomonas aeruginosa.* Originally available as a single-antibiotic agent, ticarcillin now is available only in combination with clavulanate, and piperacillin only with tazobactam. Many organisms, including MSSA, *B. fragilis, P. melaninogenica,* and many gram-negative enteric bacilli (*E. coli* and *Klebsiella* spp.) are susceptible (see Table 292.2). This allows for successful therapy for skin and skin structure infections, intra-abdominal infections, and many gram-positive and gram-negative hospital-associated infections, such as wound infections, UTIs, and pneumonia. The extended-spectrum penicillins also retain good activity against ampicillin-susceptible strains of *Enterococcus.* Tazobactam adds little to antimicrobial activity of piperacillin for *P. aeruginosa*; the combination drug is used only when coverage of additional organisms is desired.

Cephalosporins

Cephalosporins, like the penicillins, are β-lactam antibiotics found in nature. Cephalosporin C, the precursor molecule for antibiotics used in humans, originally was isolated from *Cephalosporium acremonium.* Successive modifications of the cephem ring structure have resulted in "generations" of cephalosporin antibiotics. There is no official scientific designation of generations; rather, the description of enhanced activity of the second generation over the first was created as a marketing tool.[14] However, the ability to distinguish the relative activity of the large number of cephalosporin antibiotics by generation is useful (see Table 292.2).

In general, the first-generation cephalosporins (represented by intramuscular or intravenous [cefazolin and by oral cephalexin) are active against gram-positive pathogens, group A *Streptococcus,* and penicillinase-producing *S. aureus* (MSSA), which has led to their use for skin and skin structure infections and surgical prophylaxis, as well as for systemic infections caused by these organisms. Although cephalosporins are better tolerated than the penicillinase-stable penicillins (e.g., methicillin), they are somewhat less active in vitro against *S. aureus,* and may not be as effective in the treatment of serious infections such as endocarditis. Cephalosporins uniformly lack activity against all enterococci.

The cephalosporins are active against many strains of *E. coli,* allowing treatment of urinary tract and intestinal infections. However, increasing resistance to first-generation cephalosporins has limited the usefulness of these agents in the treatment of both community-associated and hospital-associated infections.

The second-generation cephalosporins have enhanced activity against gram-negative pathogens and enhanced stability against β-lactamases compared with first-generation agents (see Table 292.2). Increased spectrum of activity includes many enteric gram-negative bacilli and β-lactamase–producing strains of *H. influenzae.* The activity of second-generation agents against MSSA is decreased, although not sufficiently to lead to clinical failures in treatment of mild to moderate staphylococcal infections. This broad spectrum of activity allows for single-drug therapy of streptococcal, *H. influenzae,* and some staphylococcal infections in children. However, because of poor penetration of the first- and second-generation cephalosporins into cerebrospinal fluid (CSF), use for the treatment of BSI is limited by *S. pneumoniae* and *H. influenzae*. Within the second generation of agents, all of which share the cephem ring structure (see Fig. 292.2), are both true cephalosporins and the cephamycins. The cephamycins were originally isolated from *Streptomyces* spp. and contain an additional side chain that enhances stability to β-lactamases, providing improved activity against β-lactamase–containing strains of *B. fragilis* (cefoxitin and cefotetan). Given reasonable activity against gram-positive organisms (except enterococci), gram-negative enteric bacilli, and anaerobes, these cephamycin antibiotics are more effective in the treatment of intra-abdominal infections than cephalosporins.

Oral second-generation agents have been used widely for the treatment of upper and lower respiratory tract infections in children. However, with higher rates of penicillin resistance in *S. pneumoniae* caused by changes in the PBP structures, treatment failures of infections caused by penicillin-nonsusceptible strains of pneumococcus using the oral second-generation cephalosporins occurs; high-dose amoxicillin therapy is superior.

The third-generation cephalosporins have further enhanced gram-negative activity, which extends to *P. aeruginosa* for ceftazidime, but at the expense of a further decrease in activity against MSSA. As with other cephalosporins, they lack activity against enterococci. Enhanced activity against enteric gram-negative bacilli has led to successful therapy of UTIs and many nosocomial infections. However, therapy of infections caused by *Enterobacter, Serratia,* and *Citrobacter* spp., which have the ability to produce chromosomally mediated (inducible) ampC β-lactamases, can fail. Failure is likely to be due to the selection of organisms at the site of infection that constitutively hyperproduce these enzymes, based on alterations in β-lactamase gene regulation, thus conferring resistance to third-generation agents.[15] In general, the third-generation cephalosporins also are hydrolyzed by extended-spectrum β-lactamases (ESBLs) produced most commonly by *E. coli* and *Klebsiella* spp.[10,16] The activity of the third-generation agents is superb against virtually all strains of *H. influenzae.* These agents, in general, achieve CSF concentrations that are effective for treatment of bacterial meningitis caused by all three major pediatric pathogens: *H. influenzae, S. pneumoniae,* and *Neisseria meningitidis.* Of note, certain penicillin-resistant strains of *S. pneumoniae* have decreased susceptibility to third-generation cephalosporins and have been associated with clinical and microbiologic failure of treatment for central nervous system (CNS) infection.[17,18] Additionally, the most active of the third-generation cephalosporins against *S. pneumoniae,* ceftriaxone and cefotaxime, have not been associated with treatment failure of respiratory tract infections caused by penicillin-resistant strains when appropriate dosing regimens are used. None of the third-generation agents should be considered optimum for the treatment of infections caused by MSSA because other cephalosporins and penicillinase-stable penicillins are more active against this pathogen.

Of the third-generation agents, ceftriaxone has a prolonged serum half-life compared with the other agents, allowing for its once-daily use for treatment of exquisitely susceptible organisms. The infrequent dosing and the ability to use either intramuscular or intravenous routes of administration have permitted outpatient therapy of serious, invasive infections at a point when the child's clinical condition is stable.[19] Caution for such use for MSSA infections is warranted because MSSA frequently is not exquisitely susceptible.

The fourth-generation cephalosporin, cefepime, maintains activity against *P. aeruginosa* and displays enhanced stability to the ampC chromosomal β-lactamases of *Enterobacter, Serratia,* and *Citrobacter* spp., while retaining significant (but not optimal) activity against MSSA (see Table 292.2).[20] This broad activity permits empiric therapy of neutropenic children with fever and allows for treatment of a wide variety of nosocomial gram-negative infections.[20–24] However, lack of activity against β-lactamase −positive strains of *B. fragilis* and against *Enterococcus* limits the ability to treat intra-abdominal infections with cefepime alone.

The fifth generation of cephalosporins, represented currently by only one available product, ceftaroline, combines the gram-negative and gram-positive activity of the third-generation cephalosporins with in vitro and clinically demonstrable activity against CA-MRSA. These agents have been designed to bind to and inactivate PBP2a, which confers β-lactam resistance in MRSA, and PBP2x, which confers resistance in *Pneumococcus,* providing clinically relevant activity against MRSA and penicillin-resistant pneumococci superior to all other currently available β-lactam agents.[25] However, ceftaroline is not active against *Pseudomonas* and is not stable to ESBLs.

Carbapenems

Carbapenems, also naturally occurring, were initially isolated from a species of *Streptomyces*, with the β-lactam moiety contained within a carbapenem nucleus (see Fig. 292.2). Carbapenems demonstrate the broadest spectrum of activity of all the β-lactam antibiotics and currently include imipenem, meropenem, doripenem, and ertapenem.[26] Carbapenems are active against both gram-positive pathogens, including MSSA but not MRSA and streptococci (with moderate activity against ampicillin-susceptible enterococci), and gram-negative pathogens (including *P. aeruginosa* for imipenem, meropenem, and doripenem), with enhanced stability against both the chromosomal ampC β-lactamases of *Enterobacter, Serratia,* and *Citrobacter* spp. and the ESBLs of *E. coli* and *Klebsiella* (see Table 292.2). They are highly active against anaerobic organisms, including β-lactamase−producing strains of *Bacteroides* and *Prevotella.* Imipenem is paired with cilastatin, a renal dehydropeptidase inhibitor that inhibits the destruction of imipenem by renal tubular enzymes, providing both an increase in the serum half-life of imipenem and a decrease in the renal toxicity of the compound. Imipenem use was associated with unexpected seizures in an open, noncomparative clinical trial in children with meningitis,[27] probably attributable to competitive inhibition of the inhibitory CNS neural pathways. Therefore meropenem, which does not produce clinically detectable CNS side effects, is the preferred carbapenem agent for treatment of CNS infections, including meningitis, brain abscess, epidural abscess, and subdural empyema. Ertapenem has the most prolonged serum half-life of the carbapenems and requires only once-daily dosing in older children (≥13 years of age) and once- or twice-a-day dosing in younger children. Carbapenems are used primarily for nosocomial infections or infections in immunocompromised hosts when exceptionally broad spectrum of activity is essential. Data support clinical and microbiologic efficacy in pneumonia, UTIs, wound infections, bone and joint infections, and skin and skin structure infections.[28] Imipenem and meropenem have been used as single-drug empiric therapy of fever and neutropenia in immunocompromised children.[21] Carbapenems provide good, but not optimum, activity against *S. aureus*. They provide the best activity of all β-lactam agents against pathogens harboring either chromosomally mediated ampC β-lactamases or ESBLs. Recent emergence of carbapenemase-producing *Klebsiella* and other carbapenem-resistant *Enterobacteriaceae* (CRE) have limited the usefulness of these broad-spectrum agents in certain regions of the world.[29] Use of such broad-spectrum agents must be weighed against the risk for promoting resistance and profoundly altering normal flora.

Monobactams

Monobactams have a unique β-lactam structure and are a naturally occurring antibiotic isolated from *Chromobacterium* spp. In contrast to penicillins, cephalosporins, and carbapenems, monobactams are not fused to an adjacent ring. Aztreonam, the only available agent in this class, has been modified chemically with side chains[30] and demonstrates gram-negative activity comparable with the third-generation cephalosporins but without significant gram-positive or anaerobic activity. Clinical use in pediatrics is limited primarily to treatment of community-acquired infections in which enteric gram-negative organisms are suspected or proven pathogens and aminoglycosides are not adequate or appropriate therapy. Aztreonam also is approved by the US Food and Drug Administration (FDA) as an inhalational antibiotic for children with cystic fibrosis who are 7 years or older, for the treatment of *P. aeruginosa* lower respiratory tract infection.

Glycopeptide Antibiotics

Glycopeptides interfere with cell wall formation in the steps that create the glycan chains before cross-linking the chains in the formation of peptidoglycan (see Fig. 292.1). Glycopeptides have a large, complex structure that consists of multiple peptides linked together into three rings, with various side-chain substitutions, including large saccharide moieties attached to the central polycyclic structure. Strong hydrogen bonds occur between a glycopeptide antibiotic and the terminal D-alanine, D-alanine dipeptide of the pentapeptide side chains of the MurNAc subunits of the glycan chain. When bound, the glycopeptides sterically prevent the transglycosylation steps required for lengthening the glycan chain.[5] Glycopeptide antibiotics are active primarily against gram-positive organisms, in which the cell wall construction occurs outside the cell membrane (see Fig. 292.3). Little activity is demonstrated against gram-negative organisms because the large structure does not cross the gram-negative outer membrane easily, preventing contact with enzymes responsible for transglycosylation in the periplasmic space. Recently documented resistance in gram-positive pathogens to vancomycin has led to intense investigation of derivatives of vancomycin and teicoplanin (another parenteral glycopeptide), leading to recent FDA approval of telavancin, dalbavancin, and oritavancin for adults. Limited data are available for these agents in children, but studies are in progress.

Vancomycin

Vancomycin is a natural product, originally isolated from *Streptomyces* spp. in 1956. Vancomycin is the only glycopeptide currently available in the United States. Originally developed to treat staphylococcal infections, vancomycin was rarely used following the availability of the penicillinase-stable penicillins, which were tolerated better. However, since the first appearance of healthcare-associated MRSA four decades ago, vancomycin has played an increasing role in the treatment of nosocomial *S. aureus* and coagulase-negative staphylococcal infections. With current prevalence of CA-MRSA, vancomycin now is used routinely for empiric therapy of serious suspected staphylococcal infections.[31,32] Decreased bactericidal activity and clinical efficacy of vancomycin compared with the penicillinase-stable penicillins for treatment of MSSA, as well as greater toxicity, make β-lactams preferred therapy for infections caused by MSSA.

Resistance to vancomycin has developed in several ways. In *Enterococcus* spp., *vanA*-mediated resistance, the most common resistance seen in clinical isolates, leads to complete resistance to vancomycin. A transmissible set of 7 genes, which encode a series of biologic functions that allow *Enterococcus* to sense the presence of vancomycin, to cleave the D-alanine, D-alanine dipeptide from the pentapeptide chain, and to substitute D-alanine, D-lactate at the terminus of the pentapeptide, results in a 1000-fold decrease in binding of vancomycin.[33,34] The new pentapeptide appears to be as viable a precursor for peptidoglycan formation as the original pentapeptide. The *vanA* resistance mechanism has now been detected in *S. aureus* infecting adults, creating vancomycin-resistant *S. aureus* (VRSA). A more common resistance mechanism of *S. aureus* to vancomycin, producing a heterogeneous population of intermediately susceptible strains or hVISA, is proliferation of the D-alanine, D-alanine glycan structures, creating a disorganized, thickened cell wall and leading to increases in the binding and trapping of vancomycin to nonfunctional dipeptides.[35–38] Under vancomycin pressure, these strains, which are present in every large population of staphylococci, are selected. However, because these strains are not fully resistant to vancomycin, retrospective data suggest that higher dosages of vancomycin (if tolerated by the patient) can remain effective therapy for hVISA.[39,40]

Three new glycopeptide antibiotics—telavancin, dalbavancin, and oritavancin—have demonstrated clinical efficacy in clinical trials in adults.[41] Modifications of the glycopeptide to enhance binding to targets, to increase stability of antibiotic binding by creating glycopeptide dimers, and to anchor the glycopeptide to the cell membrane have all been successful strategies for enhancing the activity of this class of agents. Although these newer agents have shown increased in vitro activity against *S. aureus* compared with vancomycin, prospective, controlled clinical data to document improved outcomes in adults are not available, and no data exist currently for children.

Clinical uses of vancomycin include therapy for gram-positive infections in children who are allergic to penicillin, therapy of infections caused by *S. pneumoniae* that are resistant to penicillin,[42] and therapy of infections caused by MRSA. Treatment of *Clostridium difficile* infections with orally administered vancomycin is highly effective, but is not first-line therapy because of the emergence of vancomycin-resistant enterococci (VRE) following oral vancomycin therapy. In selected cases of severe disease or metronidazole failure, vancomycin enterally represents highly effective alternative therapy.[43]

A common reaction can occur with the rapid infusion of vancomycin, the red man or red neck syndrome, characterized by flushing and hypotension. This effect is histamine mediated and not immunoglobulin E mediated or immune mediated and is distinct from anaphylaxis. The risk for red man syndrome varies directly with the rapidity of the vancomycin infusion; therefore each dose of vancomycin usually is infused over 1 hour. For children who develop red man syndrome, prolonging the infusion time or pretreating with an antihistamine may permit continuation of therapy with vancomycin.

Cell Membrane–Active Antibiotics

Daptomycin

Daptomycin, a natural product derived from *Streptomyces* spp., is a novel lipopeptide antibiotic that is rapidly bactericidal based on effects on the gram-positive cell membrane. Daptomycin has a unique structure that consists of 13 amino acids, including a cyclic peptide containing 9 amino acids, attached to a lipophilic fatty acid tail that inserts into the cell membrane. The mechanism of action of daptomycin is not well understood, but it appears that depolarization of the membrane occurs as the antibiotic polymerizes within the bacterial cell membrane, producing channels in the membrane that result in leakage of cell contents, inhibition of protein, DNA and RNA synthesis, and cell death. Based on in vitro assays, daptomycin is one of the most rapidly bactericidal antibiotics against *S. aureus* and is active against a wide variety of gram-positive organisms, including MSSA, MRSA, VRSA, resistant coagulase-negative staphylococci, streptococci, and enterococci (including VRE) (see Table 292.2).[44]

Clinical use of daptomycin has been focused on MRSA infections that are unresponsive to vancomycin. Efficacy has been demonstrated in adults and children for skin and skin structure infections and for BSI. Daptomycin is not effective for the treatment of pneumonia, based on clinical trials in which response rates were not equivalent to comparator agents. Daptomycin is inactivated by surfactant, yielding relatively low concentrations in bronchial-alveolar epithelial lining fluid and lung parenchyma.[45] Limited pharmacokinetic and clinical data have been reported in children.[46–48] The prolonged half-life allows for once-daily dosing.

In the first human clinical trials in the 1960s, daptomycin was associated with a high incidence of myalgias and muscle weakness accompanied by elevations in serum creatine kinase. This adverse effect appears to depend on the frequency of dosing. Although toxicity was prohibitive when daptomycin was administered every 6 to 8 hours, the drug demonstrated no greater toxicity than comparator agents when administered to adults in a dose of 4 mg/kg once daily.[37] When the approved dosage of daptomycin was increased to 6 mg/kg daily in adults for the treatment of BSI and endocarditis, no significant muscle toxicity was noted.[49] No muscle toxicity has been reported in any of the controlled prospective pediatric clinical trials. Toxicology studies in neonatal pups suggested a poorly defined neurologic toxicity, which resulted in a lower limit of age eligibility of 1 year in prospective comparative pediatric clinical trials. Potential risks and benefits need to be considered before use of daptomycin in neonates.

Colistin

Colistin is a polymyxin antibiotic that is a natural product isolated from *Bacillus polymyxa* and consists of 10 linked amino acids, with 6 forming a peptide ring structure attached to a fatty acid side chain. Colistin is also known as polymyxin E, structurally similar to polymyxin B, which is used extensively as a topical agent. The polymyxin antibiotics were first discovered in 1947, with the first clinical use of colistin in the US in 1959.[50] Colistin is available in the US as a sodium methanesulfonate salt, known as colistimethate. The dosage is calculated as the colistin base, at 2.5 to 5 mg/kg/day given in 2 to 4 divided doses. Colistimethate is hydrolyzed to colistin, but the rate and extent of hydrolysis and the contributions of biologic activity of the parent compound and products of metabolism are not well defined. The mechanism of bactericidal activity against the cytoplasmic membrane is based on cationic detergent activity, binding to lipopolysaccharides in the outer cell membrane, displacing calcium and magnesium and disrupting the lipid component of the cell membrane. Permeability changes subsequently occur in the membrane, disrupting the osmotic gradient of the cell and affecting cellular metabolism and nucleic acid synthesis.[51]

Colistin has been used as both intravenous and inhalational treatment for multidrug-resistant (MDR) gram-negative pathogens in children with cystic fibrosis (CF),[52] and more recently, in non-CF patients with gram-negative pneumonia.[53] For treatment of certain gram-negative CNS infections, colistin has been injected intrathecally.[54,55] Only limited, retrospective clinical data are available to guide therapy with this agent.[54,55]

Colistin has significant toxicity, primarily renal and neurologic. Renal side effects include decreased urine output with elevated blood urea nitrogen and serum creatinine, proteinuria, hematuria, and acute tubular necrosis. Because colistin is eliminated by renal excretion, it is imperative to assess renal function closely during therapy, decreasing the dosage if any degree of renal insufficiency is noted. Drug accumulation and additional renal toxicity occur if dosing is not altered when renal insufficiency first occurs. Renal toxicity usually is reversible if detected early. Neuromuscular side effects had been noted in adults and children treated with colistin in case series reported up to 50 years ago, most often manifest as oral and perioral paresthesias, weakness, lethargy, confusion, ataxia, and respiratory muscle paralysis. However, more recent experience with colistin, particularly in children, has not described this neuromuscular toxicity.[54,55]

Because of the toxicity, clinical use of parenteral colistimethate is limited to therapy of infections caused by MDR gram-negative pathogens for which no other option is available. Other clinical uses include inhaled therapy in ventilated patients with nosocomial MDR gram-negative pulmonary infections[56] and aerosolized colistimethate in children with CF as adjunctive antimicrobial therapy.[57,58]

Ribosome-Active Antibiotics

The bacterial ribosome, highly conserved over millions of years, has long been a target of antibiotics. As our ability to understand the function of the ribosome has increased, visualization of ribosomal structures with crystallography has occurred, and knowledge of the mechanism of activity of both older and newer agents, as well as ability to design more effective antibiotics, has improved substantially. The ribosome contains a 30S and a 50S subunit, each comprising rRNA and encoded ribosomal proteins. Several sites have been documented to be antibiotic targets on each subunit and at the junction of the subunits. Targets include the entry site of mRNA, the initial recognition and binding site of tRNAs, the site of attachment of the tRNA-peptide chain where peptide bonds are formed (the peptidyl transferase center), and the exit channel of the growing polypeptide.[59–61] The critical chemical and structural relationships between the ribosomal rRNA and the peptidyl transferase center, which promote the chemical reactions to create a new peptide, as well as movement of mRNA and the newly formed peptide through the ribosome, provide opportunities for interference in bacterial protein synthesis.

Macrolides

Currently available macrolides that have substantial clinical trial data for children include the erythromycins, azithromycin, and clarithromycin. All share structural similarities with either a 14-member lactone ring (erythromycin, clarithromycin) or a 15-member ring (azithromycin). All bind to at least one site in common within the peptide exit tunnel of the ribosome: domain V of the 23S RNA within the 50S subunit. To achieve activity in most bacteria, binding to a specific adenine residue of the rRNA, A2058, within this channel prevents the orderly movement of protein out of the ribosome.[62]

Clarithromycin is similar structurally to erythromycin, with only the addition of a single methyl group to the erythromycin ring, primarily conferring improved stability to gastric acid. Whereas erythromycin, clarithromycin, and azithromycin contain a cladinose carbohydrate attached to the lactone ring, a new class of ketolides, represented by telithromycin and solithromycin, substitutes a ketone in this position while adding highly charged side chains to the C11 and C12 positions. These changes both improve the binding characteristics to the peptide tunnel–binding site within domain V and create an additional unique binding site at adjacent domain II within the ribosome, improving activity against many macrolide-resistant gram-positive organisms. Azithromycin is structurally similar to erythromycin but contains a 15-member ring with the addition of a nitrogen atom within the ring itself, structurally changing the drug from a macrolide to an azalide, but containing the same side chain–attached carbohydrate moieties as erythromycin. This change improves gram-negative activity and increases gastric acid stability. The degradation products of azithromycin provide far less stimulation of gastric motility, improving the tolerability of azithromycin over erythromycin.

In general, the macrolides are inhibitory, not bactericidal, to bacteria and therefore are not used for the treatment of serious and life-threatening infections when bactericidal agents can be used. The various macrolide agents have different binding affinities for their ribosomal targets in different organisms. Binding generally is reversible, with a prolonged rate of dissociation off the ribosome potentially adding to a more prolonged postantibiotic effect seen with some macrolides (see Table 292.1).[63]

The macrolides are most active against gram-positive cocci and bacilli, and, to a lesser extent, gram-negative bacilli (see Table 292.2). Some agents also are active against spirochetes and certain mycobacteria. Pathogens that lack a formal cell wall (e.g., *Mycoplasma* and *Ureaplasma*) and are not susceptible to β-lactam antibiotics often remain susceptible to macrolides.

All of the macrolides achieve high antibiotic concentrations within phagocytic cells. These concentrations often are much higher than those measured in serum, providing access of these antibiotics to infected tissue spaces by means of neutrophils and establishing a higher tissue concentration than antibiotics that enter primarily by diffusion alone. However, presence in the intracellular location leads to less free drug available for exposure to extracellular pathogens. Macrolides are particularly effective therapy against susceptible intracellular pathogens.

In general, macrolides are well tolerated. Clarithromycin and azithromycin are better tolerated than erythromycin, which has problematic gastrointestinal side effects in some children. With the exception of azithromycin, this class of antibiotics is metabolized by hepatic cytochrome P450 system, and drug-antibiotic interactions should be considered because they may increase or decrease the macrolide and concurrent drug concentrations.[64] Azithromycin has demonstrated minimal drug-drug interactions and may represent the preferred macrolide in certain situations, particularly for immunocompromised children receiving multiple medications concurrently.

Resistance to the macrolides occurs when molecular changes occur at the critical ribosomal attachment site, most commonly a monomethylation or dimethylation of the A2058 adenine-binding site. A rapidly increasing number of recognized methyltransferase enzymes has been reported. Most are encoded by gram-positive organisms and are most often inducible, but may be constitutively produced and lead to high-level resistance to erythromycin, clarithromycin, and azithromycin.[65] Less frequent alterations at this site also affect binding, with either substitution of guanine for adenine or structural changes in the L4 ribosomal protein.[66] Efflux pumps represent another common mechanism of resistance in gram-positive pathogens, including *Pneumococcus,* group A *Streptococcus,* and *S. aureus.* The most common pumps are active against all the macrolides—erythromycin, clarithromycin, and azithromycin.[65,67]

Erythromycin

Erythromycin, a natural product isolated from *Saccharopolyspora erythraea* (formerly *Streptomyces*) in 1949, was first approved for clinical use in 1952. Erythromycin is degraded by gastric acid and has long been associated with stimulation of motilin receptors in the stomach and possibly in the colon, leading to adverse gastrointestinal side effects, including cramping and diarrhea.[68,69] Many preparations have attempted to bypass exposure of erythromycin to gastric acid, thereby avoiding products of macrolide hydrolysis. These preparations include enteric coating of orally administered tablets, delayed-release formulations, polymer coating of beads, and various formulations of salts and esters.[70] The lactobionate salt used for intravenous administration of erythromycin can cause phlebitis at the site of injection.

Erythromycin is used for the treatment of group A streptococcal infections in children who are allergic to penicillin. Erythromycin is an alternative treatment for both streptococcal pharyngitis and streptococcal or staphylococcal impetigo. The usefulness of erythromycin for respiratory tract infections caused by *S. pneumoniae* has been greatly diminished by the development of widespread resistance to the macrolides.[42] Macrolide therapy of upper respiratory tract infections (otitis media and sinusitis) or lower respiratory tract infections (pneumonia) potentially caused by *S. pneumoniae* has a relatively high likelihood of failure, particularly in younger children, who are at highest risk for infections caused by antibiotic-resistant strains. For upper respiratory tract infections, erythromycin has inadequate activity against *H. influenzae* and must be paired with another agent such as a sulfonamide for empiric therapy. Macrolides are effective therapy for pneumonia caused by *Mycoplasma pneumoniae, Chlamydophila pneumoniae,* or *Legionella pneumophila*.

Erythromycin and azithromycin are the preferred antibiotics for treatment of *Campylobacter* gastroenteritis caused by susceptible strains. Erythromycin also remains the most appropriate therapy for diphtheria (*Corynebacterium diphtheriae*). Erythromycin, clarithromycin, and azithromycin are recommended for treatment or prophylaxis of pertussis (*Bordetella pertussis*).[71] Azithromycin is preferred for treatment or prophylaxis for pertussis in neonates, based on concerns for the development of pyloric stenosis.[71] Efficacy of erythromycin also has been demonstrated in infections caused by *Chlamydophila pneumoniae* and *Chlamydia trachomatis,* including neonatal conjunctivitis and pneumonia, as well as urogenital infections during pregnancy. Erythromycin is active in vitro against *Ureaplasma urealyticum,* but its role in the treatment of neonatal infections associated with this organism is not well defined.[72]

Clarithromycin

With the improved activity demonstrated against *H. influenzae* and improved tolerability compared with erythromycin, treatment of respiratory tract infections is the most common clinical use for clarithromycin. FDA-approved indications include pharyngitis and tonsillitis, acute otitis media, acute maxillary sinusitis, and community-acquired pneumonia caused by susceptible strains of *S. pneumoniae, H. influenzae, M. catarrhalis, M. pneumoniae, C. pneumoniae,* and *L. pneumophila*. For *S. pneumoniae*, strains that are resistant to erythromycin from either methyltransferase or efflux mechanisms also are resistant to clarithromycin. The activity of clarithromycin against *H. influenzae* is modest, but in noninferiority-designed clinical trials of clarithromycin for the treatment of respiratory tract infections, the microbiologic and clinical efficacy was not significantly less than that of other approved agents.

Clarithromycin is one of the most effective macrolides for treatment and prevention of disseminated mycobacterial infections due to *Mycobacterium avium* complex (MAC) in human immunodeficiency virus (HIV)-infected persons. Although not well studied in immunocompetent children, clarithromycin may play a role in the treatment of cervical adenitis and pneumonia caused by MAC (or other nontuberculous mycobacteria proved to be susceptible in vitro), in conjunction with other antibiotics or surgery, or both.[73]

Clarithromycin plays a role in the treatment of *Helicobacter pylori* infections in combination with amoxicillin and lansoprazole, or omeprazole, or in combination with ranitidine.[74,75] Clarithromycin has demonstrated efficacy similar to erythromycin in pertussis infections in small clinical trials and is considered as one of three first-line drugs. Although approved for treatment of skin and skin structure infections, clarithromycin is not often used for this indication because other more cost-effective or more active agents are available in the treatment of infections caused by *S. aureus*. Similarly, other β-lactam and macrolide antibiotics are preferred for the treatment of streptococcal pharyngitis.

Azithromycin

Azithromycin has high intracellular concentrations and provides prolonged tissue concentrations at the site of infection, permitting administration of very short courses for respiratory tract infections. Erythromycin-resistant strains of *S. pneumoniae* also are resistant to azithromycin. Group A streptococcus has variable resistance to macrolides. Activity against *H. influenzae* is moderate, with in vitro activity increased compared with erythromycin, but decreased compared with clarithromycin. However, the relatively small differences in susceptibility may be offset by higher concentrations of antibiotic if there is an intracellular site of infection. Azithromycin also is active against the pathogens causing atypical pneumonia (see Table 292.2).

Azithromycin is far better tolerated than erythromycin, can be given once daily, and is available in both oral and intravenous formulations. Based on noninferiority-designed clinical trials, azithromycin is approved for treatment of streptococcal pharyngitis, acute otitis media, sinusitis, and community-acquired pneumonia in children. Because of prolonged tissue concentrations, particularly using larger azithromycin dosages, 5-day, 3-day, and 1-day treatment courses, all providing a total treatment dosage of 30 mg/kg, have been shown to be comparable for clinical and microbiologic outcomes with 10-day treatment courses of comparator β-lactam antibiotics in acute, uncomplicated otitis media. However, as the dose increases, the gastrointestinal tolerability of the antibiotic decreases, with vomiting and diarrhea occurring in about 10% of children receiving 30 mg/kg as a single dose.[76] Although clinical data on single-dose treatment courses for otitis media are available, randomized, comparative prospective data exist only for treatment courses of 3 and 5 days for sinusitis, and for 5 days for treatment of community-acquired pneumonia and streptococcal pharyngitis. The dosage for treatment of streptococcal pharyngitis is 12 mg/kg per day once daily for 5 days, which is larger than that for otitis media and provides a total dosage of 60 mg/kg.

Azithromycin has the widest use in children for the treatment of upper and lower respiratory tract infections. However, other uses have been documented in clinical trials, although FDA approval for many of these infections has not been sought. Treatment of pertussis has been shown to be effective in small trials.[77] Azithromycin is the recommended macrolide for prophylaxis or treatment of infants younger than 1 month and is considered equal to erythromycin and clarithromycin in older individuals.[71] Azithromycin in neonates is associated with an increased risk for pyloric stenosis, which is lower than for erythromycin. Benefits for prophylaxis or treatment of pertussis outweigh this risk.[78]

Azithromycin also is used in the treatment of sexually transmitted infections, including *C. trachomatis*–caused infections (urethritis, cervicitis, and lymphogranuloma venereum), chancroid, granuloma inguinale, and gonorrhea.[79]

Similar to clarithromycin, azithromycin has been shown to play a role in the prophylaxis and therapy of MAC infections in HIV-infected children.[80] Azithromycin also may have a role in therapy of cutaneous and lymph node infection caused by these pathogens in healthy children.

Azithromycin has enhanced activity compared with the other macrolides against many gastrointestinal pathogens, including *E. coli, Salmonella, Shigella,* and *Campylobacter*.[81] In vitro activity demonstrated against *Salmonella* is particularly advantageous given the intracellular location of this pathogen.[82] With widespread resistance among gastrointestinal pathogens to β-lactam antibiotics, fluoroquinolones, and trimethoprim-sulfamethoxazole in certain parts of the world, the utility of empiric azithromycin therapy for traveler's diarrhea has increased.[83]

Azithromycin is the only antibiotic that has been prospectively evaluated for the treatment of cat-scratch lymphadenitis.[84] However, the clinical response to treatment of lymph node disease is not dramatic, and azithromycin has not been evaluated prospectively for the treatment in other tissue sites of infection, such as liver, bone, or CNS.

Tetracyclines

The tetracyclines were derived as natural products from *Streptomyces* spp., with discovery in the 1940s and subsequent availability of two agents by 1948, chlortetracycline and oxytetracycline.[85] Tetracyclines bind reversibly to the ribosome at the aminoacyl acceptor site (A site) where the amino acid–charged tRNA binds to the ribosome immediately adjacent to the site on the ribosome holding the mRNA strand.

The aminoacyl tRNA binds to the A site together with an elongation factor (EF-Tu) and guanosine triphosphate (GTP), which supply the energy required to drive protein synthesis. The protein synthesis step includes the chemical reaction to attach the amino acid to the growing peptide chain, together with changes in the conformation of the ribosome that are associated with movement of the protein chain and the mRNA through the ribosome, followed by the subsequent release of the “empty” tRNA.[86] It appears that the flat, four-ring structure characteristic of the tetracyclines binds to at least two locations within the ribosome. Binding at the classically recognized A site appears to prevent movement of the tRNA/mRNA/EF-Tu complex into the “P site” (peptidyl site) by steric hindrance, which prevents elongation of the growing peptide. Binding to a second site in the 30S ribosome may stabilize the ribosome in an inappropriate conformation at the crucial site of recognition of the aminoacyl tRNA anticodon with the corresponding codon within the mRNA, thereby preventing placement of the correct amino acid in the elongating chain.[87] Inhibition of peptide formation by tetracyclines occurs after the binding of the tRNA to the complex and after expenditure of GTP-mediated energy, presenting the bacteria with an energy cost in addition to blocking the synthesis of a new protein.

The tetracyclines are effective against many gram-positive and gram-negative bacteria as well as against cell wall–deficient pathogens (*Mycoplasma, Rickettsia*) and certain single-cell parasites (see Table 292.2). Eukaryotic cells have elongation factors different from bacteria and are therefore not susceptible to the protein synthesis inhibition activity of this class of antibiotics. The tetracyclines enter the gram-negative cell wall through outer membrane porin proteins and are sufficiently lipophilic to allow passage through the cytoplasmic membrane of both gram-negative and gram-positive bacteria. The tetracyclines are, in general, bacteriostatic.

Resistance to tetracyclines occurred quickly following their availability for clinical use, primarily based on efflux pumps and, to a lesser extent, on the presence of ribosomal protection proteins and tetracycline-inactivating enzymes. The number of resistance genes and of bacterial species that contain them continues to increase.[85,88] These resistance mechanisms are present on plasmids, conjugative transposons, and integrons, allowing free exchange of resistance determinants between a wide range of bacteria. More than 200 different efflux pumps have been characterized, most of which are active against tetracycline, some of which also are active against minocycline, and fewer of which also are active against the most recently available tetracycline, tigecycline. The ribosomal protection proteins have sequence homologies with bacterial elongation factors present in the tRNA/mRNA/EF-Tu complex. It is believed that, as these protection proteins themselves bind to the ribosome, changes in the conformation at the tetracycline-binding site occur, preventing the binding of tetracycline but not interfering with protein synthesis. Resistance at the second 30S ribosomal binding site also has been described and is due to base substitutions in the rRNA of the 30S unit.

Advances in the design of the structure of the early tetracyclines led to doxycycline (in 1967) and minocycline (in 1972), both of which provide a greater spectrum of activity and improved solubility, creating improvements in both oral and parenteral preparations (see Table 292.2). Doxycycline and minocycline can be taken with food (with the exceptions noted later). In most cases, doxycycline and minocycline demonstrate increased activity against gram-positive organisms, and decreased activity against gram-negative organisms compared with tetracycline. Activity against *Enterococcus faecium,* but not *E. faecalis,* is achieved with newer agents. Minocycline, however, demonstrates improved activity against gram-negative organisms, including *H. influenzae, M. catarrhalis, E. coli,* and *Klebsiella* spp., compared with tetracycline, but only fair activity against *Salmonella* and *Shigella* spp. and *P. aeruginosa.* Tigecycline, a derivative of minocycline, increases the spectrum of activity against many enteric gram-negative bacilli and anaerobes, including *B. fragilis,* but still lacks a high degree of activity against *P. aeruginosa* (see Table 292.2). Historically, clinical use in pediatrics has been limited by the binding of tetracyclines to teeth and bones in growing children, leading to permanent staining of the teeth and enamel hypoplasia (and reversible long-bone growth rates in juvenile animals), the degree which is directly proportional to the number of tetracycline courses prescribed.[89,90] Doxycycline binds to calcium less readily than does tetracycline, and there has been no report of dental staining related to doxycycline use in young children. In a case-control study 58 children who had an average of 1.8 courses of doxycycline before 8 years of age were shown to have identical tooth color and enamel of deciduous teeth as did 213 unexposed controls.[91] In addition, the tetracyclines cross the placenta to expose the fetus; skeletal embryopathy in experimental animals has been noted. The oral tetracyclines cannot be taken with dairy products owing to the insoluble chelation complexes that form with calcium; similar complexes form with magnesium and iron ions. When ingested with foods containing these ions, absorption from the gastrointestinal tract is blocked.

In adults and older children, the tetracyclines have been used for the treatment of mild to moderate respiratory tract infections, skin and skin structure infections (most commonly acne), and sexually transmitted infections. Some agents in this class demonstrate activity against strains of CA-MRSA,[92] penicillin-resistant pneumococci, and VRE, and have been used in the treatment of these infections. However, few prospective, comparative data are available to assess the efficacy of tetracyclines against these pathogens, with the exception of recent studies on tigecycline (see later).

Tetracyclines are first-line therapy for infections caused by *Rickettsia* (most notably Rocky Mountain spotted fever) in infants and children of all ages,[91,93] *Ehrlichia,* and *Anaplasma* spp., tularemia (oral therapy for less severe infections), brucellosis (with rifampin), cholera, *Chlamydia* genital infections, and Lyme disease (*Borrelia burgdorferi*) in older children.

Tigecycline

Tigecycline is a chemically modified minocycline, with the addition of a *t*-butylglycylamido side chain to the C9 carbon of the "D" tetracycline ring.[94] Tigecycline is not affected by the majority of efflux pumps and ribosomal protection proteins that decrease the activity of other tetracyclines. Tigecycline has a higher binding affinity to the ribosomal binding site than the previous tetracyclines[85] and has a broader spectrum of activity than any other tetracycline agent (see Table 292.2). In rat models, bone discoloration was documented, suggesting that tigecycline forms calcium complexes in bone similar to other tetracyclines.

In adults, tigecycline is approved for treatment of complicated skin and skin structure infections and complicated intra-abdominal infections given its activity against enteric gram-negative bacilli and anaerobes, including *B. fragilis.* Tigecycline retains activity against the agents of atypical pneumonia that is equivalent to, or better than, earlier tetracyclines.

The ultimate clinical role of tigecycline has yet to be defined in the treatment of nosocomial infections caused by MDR gram-negative and gram-positive organisms that remain susceptible to tigecycline. For children, the risks for bone toxicity and tooth staining need to be balanced with the benefits of therapy, particularly for drug-resistant pathogens. For situations in which no alternatives exist, the tetracyclines represent effective therapy.

Lincosamides

The lincosamides are naturally occurring compounds derived from *Streptomyces* spp. Clindamycin, approved in 1966, is the only lincosamide available in the US and is a semisynthetic derivative of lincomycin. The lincosamide antibiotics bind to the 50S subunit at a site that overlaps both the A and P sites on the ribosome, preventing the docking of charged tRNAs and their movement through the peptidyl transferase center, thus inhibiting the formation of protein. The P-site attachment of clindamycin occurs at the same ribosomal-RNA structural bases as the macrolide binding sites (A2058, A2059), explaining the competitive inhibition between binding of the two classes of antibiotics for the ribosome, as well the resistance that occurs to both antibiotics by altering a single base.[95] The lincosamides generally are considered bacteriostatic, although bactericidal activity can be demonstrated against certain organisms at antibiotic concentrations 2 to 4 times the minimum inhibitory concentration (MIC).[96]

Resistance to the lincosamides occurs primarily in bacteria that constitutively produce the methyltransferase that monomethylates or dimethylates the A2058 adenine present at the outlet of the ribosomal peptidyl transferase center. Enzyme can be induced, most often in the presence of the appropriate substrate, usually a macrolide. In contrast, the lincosamides appear to be poor inducers of the methylase enzyme. Therefore organisms that have inducible resistance may remain susceptible to clindamycin, even after exposure to the antibiotic. However, genetically altered strains that have lost gene regulation and constitutively produce methylase occur at a rate of approximately 1 in 10^7 *S. aureus;* selection of constitutive mutants can occur during therapy, with subsequent treatment failure.[67,97] This situation is most likely to occur in serious, deep, high-density bacterial infections, but not with mild to moderate skin infections or cutaneous and soft tissue abscesses that can be incised and drained. The commonly encountered efflux pumps that are active against the macrolides are not active against clindamycin.

High intracellular concentrations of clindamycin in phagocytic cells are believed to be beneficial in certain clinical infections.[98] However, no prospectively collected data have confirmed the benefit in clinical or microbiologic cure of infection as a result of either improved intracellular killing of organisms such as staphylococci or improved delivery of clindamycin to the site of infection through phagocytic cell migration.

Clinical use of clindamycin has changed substantially over the past decade. Commonly used for its activity against anaerobes in the treatment of intra-abdominal infections such as appendicitis, clindamycin resistance of *B. fragilis* has increased, and clindamycin no longer is recommended as the anaerobic agent of choice.[99,100] Clindamycin continues to have a good spectrum of activity for use in deep head and neck space infections, dental abscesses, and aspiration pneumonia (with or without empyema). Less common uses continue for treatment of gram-positive cocci, such as failures of penicillin in group A *Streptococcus* pharyngitis, and for treatment of *S. aureus* infections due to susceptible organisms.

In the early 1990s, the emergence of penicillin- and macrolide-resistant *S. pneumoniae* causing upper and lower respiratory tract infections promoted the use of clindamycin in the treatment of mild to moderate respiratory tract infections in children. Low levels of clindamycin resistance have been reported. Although no formal, randomized prospective comparative studies were performed in acute otitis media, sinusitis, and pneumonia, clindamycin has been recommended for treatment of infection due to penicillin-resistant pneumococci.[101]

The emergence of CA-MRSA in the mid-1990s dramatically increased the use of clindamycin for skin and skin structure infections and bone and joint infections. Although most published data on the efficacy of clindamycin in the treatment of MRSA are retrospective, clindamycin appears to be effective for these pathogens.[102,103] Some regions of the US in which MRSA is prevalent have documented decreasing resistance to clindamycin due to spread in the community of certain clindamycin-susceptible clones,[83] but other areas can experience increasing clindamycin resistance, particularly with methylase-harboring organisms that confer resistance to both clindamycin and macrolides. Many hospital laboratories now report strains that test susceptible in vitro, but carry the methylase gene as "resistant," leading to an "increase" in resistance based on changes in how resistance is reported. Susceptibility of MRSA and MSSA should be assessed locally to guide empiric therapy for serious infections.[104,105]

The ability of clindamycin to target ribosomal protein production has led to use in the treatment of toxin-mediated infections caused by *S. aureus* (toxic shock syndrome) and *S. pyogenes* (toxic shock −like illness), either alone or in combination with a cell wall−active antibiotic agent. In vitro data and retrospectively analyzed human data suggest some benefit of combined therapy.[106]

The principal adverse event associated with clindamycin is a direct function of its activity against normal anaerobic gastrointestinal flora—diarrhea.[85] *C. difficile*−mediated pseudomembranous colitis is a potential complication of virtually any broad-spectrum antibiotic, including clindamycin.[107] Accurate, prospectively collected data on the incidence of *C. difficile* enterocolitis are not available for clindamycin-treated children, but there are not increasing reports of enterocolitis associated with the broad use of clindamycin for pneumococcal and staphylococcal infections.

Aminoglycosides

The aminoglycoside/aminocyclitol class of antibiotics is derived from *Streptomyces* spp. and *Micromonospora* spp. In general, these antibiotics contain a 2-deoxystreptamine ring attached to two or three additional moieties, most often amino sugars, all connected together by glycosidic linkages. Medicinal chemists have created substitutions at up to 10 different positions on the three rings or associated amino groups that have led to the creation of several semisynthetic aminoglycoside antibiotics. However, given the nephrotoxicity and ototoxicity inherent to aminoglycosides, little activity has occurred in the development of newer agents for community infections, although broader spectrum agents have been recently developed for MDR gram-negative pathogens. All aminoglycosides currently available in the US are generic formulations, with gentamicin, tobramycin, and amikacin representing those most often used in children.

All of the aminoglycoside antibiotics share a common binding region within the 30S ribosome, which is located at the peptidyl transferase center where charged tRNAs are first recognized and attach to the A site. With aminoglycoside binding close to the A site, conformational changes occur at the ribosomal tRNA docking site that create enhanced affinity for tRNA binding, facilitating incorrect binding of noncognate tRNAs that do not match the corresponding codon on the mRNA. With attachment of incorrect tRNAs, misreading occurs and amino acid sequences in the resulting peptide are incorrect, leading to the creation of nonfunctional proteins. With binding of the aminoglycoside, proofreading for the accuracy of the attached tRNA also is compromised because subsequent conformational changes that should occur in the 30S unit to allow for exact recognition of the attached tRNA cannot take place.[86,108–110] The structures of two of the larger aminoglycosides, streptomycin and spectinomycin, allow for additional binding sites within the 30S ribosome. Streptomycin attaches at four different domains within the 30S rRNA, as well as having a unique attachment to one of the ribosomal proteins. Spectinomycin, a larger structure with fused rings, appears to bind at the A site in a unique manner that also blocks the movement of the aminoacyl tRNA/peptidyl tRNA/EF-Tu complex from the A site to the P site during the peptidyl transferase reaction. With the production of abnormal proteins that may be incorporated into cellular structures such as the cell membrane, increased permeability of the membrane occurs. With increased permeability, the aminoglycosides demonstrate enhanced entry into the cells, allowing further saturation of aminoglycoside binding sites on the ribosome, thus preventing the formation of new, functional ribosomes, which ultimately results in cell death. The aminoglycosides are bactericidal and show concentration-dependent killing of bacteria (see Chapter 291).

Resistance to aminoglycosides occurs primarily with the acquisition of a variety of aminoglycoside-modifying enzymes, many of which are carried on plasmids and transposons for efficient spread between bacteria. The most common are acetyltransferases, adenyltransferases, and phosphotransferases.[109] Many different efflux pump systems also play a major role in aminoglycoside resistance, particularly in gram-negative bacilli.[109] Ribosomal RNA methylase genes from *Actinomyces* that confer resistance to aminoglycosides recently have been identified in clinical isolates of enteric gram-negative bacilli and *P. aeruginosa*.[111] Although this mechanism of resistance currently is uncommon, these genes now have the potential to spread quickly within clinical settings.

The clinical use of aminoglycosides is primarily for the treatment of aerobic gram-negative bacillary infections—from the premature neonate through the adolescent.[112–114] Aminoglycosides are strongly polar, with high solubility in water but poor solubility in lipids, resulting in poor penetration into the CNS, vitreous, bronchial secretions, and saliva. Aminoglycosides are concentrated in the proximal renal tubules and excreted in urine and achieve urinary tract concentrations up to 100 times the serum concentration. Because of the toxicity of the aminoglycosides at serum concentrations that are only 5- to 10-fold above the bacterial MICs, they are not usually used as the sole agents for treatment of serious infections. The aminoglycosides frequently are paired with a β-lactam antibiotic to create synergistic antibacterial activity and potentially to retard the emergence of antibiotic resistance, although the clinical effect of combination therapy has not been well demonstrated beyond the immunocompromised host.[115] Empiric and definitive therapy of early- and late-onset neonatal septicemia with gentamicin-containing combinations for enteric gram-negative infections is still appropriate three decades after the first recommendations in this age group, although well-controlled, prospective, comparative studies generally have not been performed.[112,113,116] Therapy of nosocomial infections with aminoglycoside-containing regimens is appropriate in institutions in which nosocomial gram-negative pathogens remain susceptible.[117]

For gram-positive infections, the aminoglycosides add enhanced bacterial killing to cell wall–active agents, particularly in the treatment of serious infections.[118] Enterococcal infections are treated with ampicillin or vancomycin in combination with gentamicin to achieve bactericidal activity. The combination of penicillin plus gentamicin, or nafcillin plus gentamicin, is considered by some experts to be the most effective therapy for infective endocarditis caused by susceptible strains of viridans streptococci and *S. aureus*, respectively, especially for initial therapy.[119] However, controversy exists over the role of aminoglycosides in combination therapy because clinical benefits have not been documented to be substantial, whereas renal toxicity is not uncommon.[120]

Empiric therapy of nosocomial infections and infections in immunocompromised hosts has included combination regimens containing aminoglycosides to enhance the spectrum of β-lactam agents, to provide potential synergy, and to minimize the emergence of resistant pathogens.[21] Aminoglycosides also are used in combination with other agents in the treatment of intra-abdominal infections. However, the charges on the aminoglycoside molecule change as the pH changes in infected tissues, with the acidic environment of an abscess increasing protonation and decreasing the ability of these antibiotics to enter bacterial cells (as documented by MICs at low pH that can be higher than those safely achievable in serum).[121] In addition, the active transport of aminoglycosides through the inner cell membrane into the cytoplasm of the bacteria requires an oxygen-dependent transport system not present in anaerobes, explaining the lack of activity of this class of agent in the treatment of anaerobic infections.

Given the high level of activity against certain gram-negative pathogens and lack of current prospective treatment trials using newer agents, the aminoglycosides still represent preferred therapy for tularemia and plague.

Streptomycin remains highly active against most strains of *M. tuberculosis* requiring parenteral therapy, which leads to use in treatment of MDR tuberculosis. Streptomycin may be particularly useful in the treatment of serious, life-threatening tuberculosis, including tuberculous meningitis. Although originally approved for use in 1952 and previously important for the treatment of infections caused by *Brucella* and *Francisella* spp., streptomycin has been replaced by gentamicin because of concerns for streptomycin-induced vestibular, auditory, and renal toxicity.

Paromomycin is an oral, nonabsorbable aminoglycoside. This agent is effective in the treatment of intestinal protozoal infections, including amebiasis and cryptosporidiosis.

Inhaled aminoglycosides, most commonly tobramycin, are used clinically to treat cystic fibrosis. Achieving high enough antibiotic concentrations in respiratory tract secretions and at the bronchial mucosa to be effective against *P. aeruginosa* is not usually possible with parenterally administered aminoglycosides, but high concentrations can be achieved with inhaled tobramycin, without concern for nephrotoxicity or ototoxicity.[122] The use of aerosolized aminoglycosides in patients with pneumonia caused by other MDR gram-negative pathogens has not been prospectively investigated in controlled studies, but case series in adults suggest their potential role.[123]

Nephrotoxicity of aminoglycosides is dose dependent and primarily is tubular. Monitoring renal function or aminoglycoside serum concentrations during therapy permits early detection of decreased renal function attributable to the aminoglycoside. Aminoglycoside ototoxicity can be either cochlear (with hearing loss) or vestibular (with vertigo) and correlates with increasing serum trough concentration as a function of overall drug exposure, rather than the peak serum concentration.[124]

Providing children with a single daily dose of aminoglycosides to decrease nephrotoxicity while maintaining or increasing efficacy has not been widely accepted because of the lack of well-controlled studies in children. However, limited data that exist in children, taken together with convincing data in adults, suggest that once-daily dosing could become routine for children, except possibly for certain severe infections, such as meningitis or persistent BSI.[125,126]

Although streptomycin was the first aminoglycoside available for use, the toxicity and rapid development of resistance in bacteria limited its longterm viability. Kanamycin was approved for use in 1957 but was replaced by the less nephrotoxic gentamicin in 1963 as a more broadly active antibiotic against resistant gram-negative pathogens. Tobramycin was approved in 1968 and provided a small but predictable increase in in vitro activity against *P. aeruginosa,* with a concomitant small but clinically insignificant decrease in activity against enteric gram-negative bacilli, allowing its use as the anti-pseudomonal aminoglycoside of choice. Amikacin, a semisynthetic derivative of kanamycin, was approved in 1972 and offered enhanced activity against many gentamicin- and tobramycin-resistant pathogens, in addition to providing serum antibiotic concentrations approximately 3- to 4-fold greater than those achievable with gentamicin or tobramycin. Amikacin also is useful in the treatment of infections caused by some strains of nontuberculous mycobacteria.

Streptogramins A and B

The streptogramins are two of a series of naturally occurring antibiotics isolated from *Streptomyces pristinaespiralis.* Two antibiotics have been modified from the naturally occurring pristinomycins I and IIA to create the semisynthetic antibiotics quinupristin (streptogramin B) and dalfopristin (streptogramin A), respectively. These two antibiotics are present in the FDA-approved combination Synercid in a 70 : 30 ratio.[127] Quinupristin and dalfopristin have completely different chemical structures, each with a distinct but overlapping binding region within the P site of the peptidyl transferase center in the ribosome. Binding of dalfopristin to this region produces a conformational change that significantly increases the affinity of binding of quinupristin, in part explaining the synergy observed when the combination is used. Dalfopristin inhibits protein synthesis by interfering with substrate attachment to both A and P sites of the 50S subunit, whereas quinupristin blocks peptide bond synthesis during elongation by causing incorrect positioning of the peptidyl tRNA at the P site.[128] When elongation has been initiated, quinupristin triggers the premature release of the elongating peptide chain. Quinupristin binds to the peptidyl transferase site at a similar location as the macrolides and lincosamides; methylation of the A2058 adenine at this important binding site prevents binding of quinupristin as well as the macrolides and clindamycin, and creates the macrolide-lincosamide-streptogramin (MLS) resistance phenotype.

Unfortunately, many mechanisms of bacterial resistance limit the clinical utility of quinupristin-dalfopristin, with resistance developing in some patients soon after starting therapy. Alterations of target binding sites, efflux removal of antibiotics from cytoplasm, and enzymatic alteration of the antibiotic structure all have been reported.[65,129] Although each of the streptogramins independently produces inhibitory effects on protein synthesis, the combination is bactericidal for a number of gram-positive pathogens, including *S. aureus.*

The agents have been available in Europe for several years as topical therapy, but with the development and spread of enterococci that are resistant to vancomycin, β-lactams, and aminoglycosides, an urgent need for quinupristin-dalfopristin was well documented. Clinical use is largely limited to serious infections caused by vancomycin-resistant strains of *E. faecium* (VRE). The combination is not active against the more common enterococcal pathogen, *E. faecalis.*

Quinupristin-dalfopristin significantly inhibits cytochrome P450 CYP3A function and can affect serum concentrations of concomitant drugs that are eliminated by this pathway. Phlebitis was a major side effect in quinupristin-dalfopristin–treated patients, occurring in almost half of adults receiving therapy. This combination agent has not been studied systematically in children younger than 16 years.

Oxazolidinones

Linezolid is the first antibiotic in the oxazolidinone class to be approved and used in children. This class of antibiotics is unique in that members are not natural products, but were discovered as one of a number of compounds created as potential monoamine oxidase (MAO)-inhibiting agents.[130] However, some of these compounds also demonstrated antibacterial activity, although initially, many were associated with significant toxicity. Subsequent chemical modifications led to the development of linezolid, which demonstrated a reasonable balance between antimicrobial activity, clinical efficacy, and acceptable clinical toxicity. The oxazolidinones have a unique mechanism of action on the ribosome, distinct from all other classes of antimicrobial agents. The antibiotic binds to an area close to the ribosomal peptidyl transferase center and inhibits the initiation of protein synthesis by preventing the formation of the initiation complex of fMet-tRNA/elongation factors/mRNA/GTP. The movement of the complex from the ribosome's “A site” of tRNA attachment to the peptidyl “P site” is blocked, and coupling of amino acids and lengthening of the peptide chain cannot occur.[131]

Linezolid demonstrates bactericidal activity against *S. pneumoniae,* but bacteriostatic activity against *S. aureus* and *Enterococcus* spp. However, limited studies comparing vancomycin, a bactericidal agent (with limitations in activity in infected lung) with linezolid in the treatment of nosocomial pneumonia caused by MRSA documented superiority in clinical outcomes with linezolid.[132,133] Activity of linezolid is primarily limited to gram-positive bacteria, owing to the presence of an efflux pump (AcrAB) present in many gram-negative organisms. Linezolid is not active against *Mycoplasma* or *Ureaplasma*.[134]

Resistance to linezolid has been described and consists of structural changes at the linezolid binding site that prevent attachment.[65,135] These relatively infrequent changes, which tend to occur more often with more prolonged therapy, are primarily single-base changes in the rRNA occurring around the peptidyl transferase site. Transferable resistance to the oxazolidinones through conjugative transposons has been documented.[65]

Linezolid has been studied clinically for nosocomial and community-acquired pneumonia and for complicated and uncomplicated skin and skin structure infections.[136,137] The clinical and microbiologic response rates for each of these tissue-specific infections in children were equivalent to comparator agents, usually vancomycin. The in vitro activity and clinical efficacy of linezolid in the treatment of infections caused by penicillin- and macrolide-resistant pneumococci, VRE, MRSA, and VRSA support a role for linezolid when other, better-studied agents are not available or are not tolerated. The most common current clinical use of linezolid in children is for the treatment of MRSA-associated skin or respiratory tract infections.[138] Few data other than case reports are available for the use of linezolid in treatment of bone and joint infections[139] and CNS infections.[140]

Data on pharmacokinetics for both parenterally and orally administered linezolid are available in children, including premature neonates.[141] Linezolid is virtually 100% absorbed by the oral route, allowing equivalent mg/kg dosing for both intravenous and oral formulations. Linezolid is not metabolized by the cytochrome P450 system and does not induce this enzyme or compete with other drugs in P450-mediated metabolism. Some concerns have been raised regarding hematologic toxicity, including neutropenia and thrombocytopenia, which was found to be dependent on dose and duration of therapy.[130] However, prospective, comparative data in the pediatric FDA registration studies failed to demonstrate a significant difference in toxicity compared with other agents. Optic and peripheral neuropathy has been reported with longterm use in children.[142] The possibility of hypertension due to effects of the antibiotic's mild MAO inhibitor activity were monitored carefully in early pediatric clinical trials. No MAO inhibitor side effects were noted in any phase 1 to 3 pediatric trial, permitting children to remain on usual diets while receiving treatment.

Nucleic Acid–Active Antibiotics

RNA Polymerase

Rifamycins

The rifamycins, rifampin (also called rifampicin), rifabutin, rifapentine, and the oral nonabsorbed rifaximin, are all semisynthetic derivatives of natural products of *Streptomyces* spp. The intracellular target for the rifamycins is DNA-dependent RNA polymerase and has been well defined on a molecular level.[143] During the creation of an RNA strand from the bacterial DNA strand, the polymerase requires functional channels within the enzyme for both the DNA template strand and complementary strand, as well as for the elongating RNA strand. As the RNA bases dock sequentially at the active site within the polymerase, the newly created RNA strand moves forward, one base at a time. The rifamycins bind in the channel occupied by the newly created RNA strand, approximately 2 to 3 bases downstream from the active site, blocking the RNA strand from moving out of the polymerase and terminating the further elongation of that RNA segment as it also uncouples the RNA strand from the active site.[143,144] Although the actual active site of the polymerase is highly conserved between bacterial species, there is some diversity between bacteria around the active site with respect to the RNA polymerase structure. This diversity alters the binding affinity for rifampin across bacterial and mycobacterial species and provides one basis for the variable susceptibility. Rifampin demonstrates bactericidal activity against susceptible organisms.

Given the large size of the rifamycin molecule, multiple binding sites within the polymerase, and the restricted target binding pocket in the polymerase, it is not surprising that many different single amino acid substitutions from mutational events within the polymerase lead to decreased rifamycin binding and stable resistance with little effect on the viability of the organism. In *S. aureus,* at least 18 genotypes resistant to rifampin have been characterized, some of which contain multiple base substitutions.[145] Each of these mutations is likely to affect either the binding affinity or the access of rifampin to the binding pocket to a different degree. Most mutations causing rifampin resistance also produce resistance to rifabutin and rifapentine.[146]

The rifamycins have a remarkably broad spectrum of activity that includes *Staphylococcus* spp., *S. pyogenes, Neisseria* spp., *H. influenzae, Campylobacter jejuni, H. pylori, C. trachomatis,* both tuberculous and nontuberculous *Mycobacterium* spp., *Aspergillus* spp., *Naegleria fowleri,* and *Toxoplasma gondii* (see Table 292.2). Rifabutin has increased in vitro activity against *M. tuberculosis* compared with rifampin, but has not been documented to result in improved microbiologic outcomes in treated patients.[147] Rifabutin also has increased activity against MAC compared with rifampin, most likely because of binding to additional sites within the polymerase.[143,148] Rifapentine has both increased in vitro activity against *M. tuberculosis* in addition to an extended serum elimination half-life (16 hours) compared with rifampin (2 to 3 hours). Once-weekly rifapentine for 12 weeks is as effective as 9 months of daily isoniazid in the treatment of latent tuberculosis.[149]

Rifamycins achieve high intracellular concentrations, between 5- and 20-fold greater than extracellular concentrations.[148] This likely explains the effectiveness of this class in the therapy for mycobacterial infections, in which pathogens are sequestered intracellularly.

Of the rifamycins, rifampin is the agent most commonly used in pediatrics, usually as part of combination therapy for active tuberculosis. Rifampin also can be used in combination therapy for treatment of nontuberculous mycobacterial infections such as lymphadenitis, cellulitis, or pneumonia. For treatment of bacterial infections, rapid emergence of resistance in virtually every pathogen dictates a need for combination antibiotic therapy. Combination therapy may allow for eradication of rifampin-resistant strains before they become clinically important. Rifampin has been used in combination therapy for *Bartonella henselae* infections (cat-scratch disease), *S. aureus* infections (particularly MRSA), and MDR pneumococcal infections, including meningitis.[150] Although not well studied in prospective comparative clinical trials, the excellent tissue penetration of rifampin may provide improved clinical outcomes compared with β-lactam antibiotic therapy alone in deep bone and joint infections and in foreign-body or biofilm-associated infections, such as on intravascular catheters or implanted devices. As single-drug therapy, rifampin is only used when prophylaxis for *N. meningitidis* and *H. influenzae* type b infections is indicated.

Rifabutin has documented efficacy in both prophylaxis and therapy of MAC (in combination with other agents) in HIV-infected adults, but clarithromycin and azithromycin are recommended as preferred therapy for HIV-infected children.[80] Only limited data are available in children with MAC infections.[73,151,152] The extended half-life of rifapentine provides a rationale for once-weekly therapy, although the failure rate in those with more serious active tuberculosis and the bacteriologic relapse rate were slightly higher in those treated with rifapentine compared with rifampin.[147,153]

Rifaximin is an oral agent that is not absorbed from the gastrointestinal tract and produces high intraluminal antibiotic concentrations with little systemic toxicity. Microbiologic activity has been demonstrated in vitro at achievable intraluminal antibiotic concentrations against *E. coli, Salmonella, Shigella, Vibrio, Yersinia,* and *Campylobacter* spp. Although the MICs for these enteric pathogens is about 32 to 64 μg/mL, a concentration not achievable in tissues, the concentrations achieved in the gastrointestinal tract are as high as 8000 μg/mL, well above that required for antibacterial effect.[154] Although rifaximin antibiotic is currently only approved for traveler's diarrhea in adults,[155] an oral nonabsorbable, broad-spectrum agent for other gastrointestinal pathogens could have considerable value for children.

The most common clinical side effect of treatment with rifampin is nausea, which appears to decrease as the treatment course progresses. The most common adverse effect of treatment is hepatotoxicity, as assessed by elevation of hepatic transaminase levels; however, most children receiving rifampin for tuberculosis therapy also receive other hepatotoxic agents, preventing accurate assessment of a singular role of rifampin in liver injury.[156] Children receiving multiple hepatotoxic agents should be assessed at regular intervals for evidence of hepatic injury.

The drug-drug interaction profile of the rifamycins frequently complicates clinical management. The P450 CYP3A system is activated by the rifamycins. If the child is receiving another drug metabolized by this system, decreased, potentially ineffective serum concentrations of that drug may be present. In addition, if the concurrent drug represents a competitive substrate for P450 metabolism, increased and potentially toxic serum concentrations of that drug can result from decreased metabolism.[148] The potency of CYP3A induction is greatest with rifampin and least with rifabutin. Rifabutin is also a CYP3A substrate itself, resulting in higher rifabutin serum concentrations when given concomitantly with CYP3A inhibitors.

DNA-Dependent DNA Polymerase

Quinolones and Fluoroquinolones

The quinolones are a diverse group of antibiotics that target DNA synthesis and are active against a wide range of bacteria, *Mycoplasma, Chlamydia,* and *Chlamydophila* spp., and, for certain agents, mycobacteria.[157,158] The first of the quinolone antibiotics was discovered during the commercial preparation of the antimalarial agent chloroquine, and was modified subsequently for antibacterial use in humans.[157] The first approved quinolone agent, nalidixic acid, has a limited gram-negative spectrum of activity and a poor pharmacokinetic profile for treatment of tissue invasive infections. With chemical modifications to the basic quinolone (and the closely related naphthyridone) ring structure, the spectrum of activity and pharmacokinetics have been enhanced greatly, allowing for once-daily dosing for infections in many different tissue sites. The 6-fluoroquinolones (beginning with norfloxacin and ciprofloxacin) demonstrated a significant improvement in antibacterial activity, and virtually all subsequently approved compounds are fluoroquinolones.

The quinolones all interfere with DNA synthesis by interfering with two closely related type II topoisomerase enzymes involved in DNA synthesis: DNA gyrase and topoisomerase IV.[158,159] Each of these enzymes comprises 4 subunits: DNA gyrase contains 2 subunits of GyrA and 2 of GyrB, whereas topoisomerase IV consists of 2 subunits of ParC and 2 of ParE (in *S. aureus,* these topoisomerase IV subunits are termed GrlA and GrlB). The DNA gyrase is responsible for uncoiling DNA ahead of the replication fork to allow for DNA strand replication by DNA polymerase, or for the creation of RNA strands by RNA polymerase. In the process of uncoiling and coiling, strands of DNA are cut and then religated by these enzymes to maintain a stable double-helix structure. The topoisomerase IV appears to be primarily responsible for stabilizing the newly created strands of DNA as they separate from template strands after replication. The quinolones bind to these enzymes at specific nucleic acid strand attachment sites, producing conformational changes in the DNA gyrase/DNA or topoisomerase IV/DNA complexes and stabilizing them, thus “freezing” the complex. This leads to an inability to translocate the entire DNA replication complex along the DNA strand, halting the process of nucleic acid replication. Binding of the fluoroquinolones leads to single- and double-stranded DNA breaks without religation, and the subsequent release of DNA fragments into the cell, which leads to cell death in ways that are not well understood. The DNA gyrase/DNA replication complex may also be involved in altering the formation and stability of DNA loops involved in the transcription process, representing another mechanism by which fluoroquinolones affect cell function.

Although quinolones can bind to some extent to both gyrase and topoisomerase enzymes, structural characteristics of each quinolone create unique binding characteristics to each of these two enzymes for every drug in this class. The differences in binding to DNA gyrase and topoisomerase IV lead to differences in the susceptibility of organisms to the various quinolones as well as differences in the development of resistance. In general, the quinolones preferentially bind to DNA gyrase in gram-negative bacteria and to topoisomerase IV in gram-positive bacteria, although some of the newer quinolones bind to both enzymes equally well. Binding to DNA gyrase, occurring before the replication fork of DNA synthesis, produces a more rapid effect on the formation of DNA, whereas binding to the topoisomerase IV after strand duplication has occurred creates a less immediate effect on cell death. However, because both enzymes function to nick and religate strands of DNA during the coiling/uncoiling process, the quinolone effects after binding to either, or both enzymes, can lead to cell death. These agents display bactericidal activity against bacterial pathogens, with dose-dependent pharmacodynamic activity best described by the ratio of the area under the serum concentration−time curve to the MIC of the antibiotic for that organism (AUC:MIC).[160]

Resistance can develop in many different ways, and resistance from multiple different mechanisms can be additive. Most commonly, resistance occurs from alterations in the amino acids present at certain critical and virtually identical sites on the two enzymes, DNA gyrase, and topoisomerase IV, that prevent avid binding of the quinolone. Single-gene mutations leading to these amino acid changes are found primarily in the quinolone resistance −determining regions of *gyrA* and *parC*.[161] Additional, less common mutations have been detected in *gyrB* and *parE.* For *E. coli,* accumulating additional amino acid changes lead to increasing resistance. The first-step mutation in *E. coli* most often occurs in the *gyrA* subunit of DNA gyrase, leading to a mild to moderate increase in MIC, depending on the quinolone being assessed. A second-step mutation, usually in *parC,* generally leads to resistance that cannot be overcome at achievable tissue concentrations. For *S. pneumoniae* and *S. aureus,* the first-step mutation most often occurs in the *parC* (or *GrlA*) subunit of topoisomerase IV.[161,162] Depending on both drug and bacteria, mutations in one of the subunit sites can lead to substantial increases in resistance for a particular drug, but for drugs that bind to both gyrase and topoisomerase IV sites, a mutation at one site does not effectively raise the MIC to a level that usually leads to treatment failure. When two or more mutations occur that affect binding to both enzymes, clinical failures become more common.

Efflux pumps also are effective mechanisms to prevent quinolone binding intracellularly to the gyrase and topoisomerase targets. Efflux pumps affect intracellular concentrations of different quinolones to differing degrees.[162] In addition, newly described mutations in aminoglycoside acetyltransferases confer the ability to acetylate ciprofloxacin, decreasing its activity against *E. coli* twofold to fourfold, with the modified enzyme still retaining activity against the aminoglycosides. This mechanism of resistance is transferable to other bacteria, in contrast to the *gyrA* or *parC* mutations, which only spread horizontally from patient to patient. It is not known how problematic these strains will become.[163]

Safety issues for children have been a concern for this entire class of agents. Although nalidixic acid was approved by the FDA for use in children in 1963, more extensive animal toxicology studies were available for the agents that followed. Preclinical juvenile animal toxicity data for ciprofloxacin in the late 1970s documented the potential for damage to joints in young beagle pups. Therefore no routine pediatric drug development was undertaken for ciprofloxacin or any other fluoroquinolone until the need for potential use in children was demonstrated to the FDA in 1997.[164] No quinolone-associated arthropathy has yet been documented clearly in children for agents available in the US, although a suggestion of transient arthralgia exists from an FDA safety database of ciprofloxacin.[165] Longterm 5-year prospective toxicity studies did not document an increased rate of musculoskeletal adverse events above that seen in comparator antibiotics in clinical trials of levofloxacin for respiratory tract infections in children.[166] Although these studies were not scaled to detect or define rates of rare adverse effects on joints or tendons, lack of reported toxicity from current published data and from data presented to the FDA suggests that joint toxicity is not a common problem in children, if it exists at all.

Nalidixic Acid, Norfloxacin

Nalidixic acid was approved in 1963 for use in children as young as 3 months for the treatment of UTI. Norfloxacin, used for treatment of UTIs in children in other areas of the world, is not approved by the FDA for children in the US.

Ciprofloxacin

Ciprofloxacin was one of the first of the 6-fluoroquinolones to be approved by the FDA for adults, but large clinical trial investigations in children did not begin until the late 1990s, with the exception of studies in children with CF. Ciprofloxacin was studied for complicated UTI and was the first 6-fluoroquinolone to have limited approval by the FDA for use in pediatrics in 2004. Based on the quality of prospectively collected data regarding both safety and efficacy in children, ciprofloxacin is the preferred quinolone agent for UTIs when a fluoroquinolone is needed. Although all of the fluoroquinolones have a bitter taste, a tolerable suspension formulation of ciprofloxacin is available for children. Current use of the fluoroquinolones is limited, based on concerns of cartilage toxicity. Antimicrobial activity of ciprofloxacin (see Table 292.2) includes most of the enteric gram-negative bacilli as well as *P. aeruginosa.* Activity against the gram-positive pathogens and anaerobic pathogens generally is only fair.

Current qualifying clinical use of ciprofloxacin centers on gram-negative infections for which no other oral antibiotic agent is available.[165,167] In this setting, ciprofloxacin and other fluoroquinolones represent effective therapy in which the risk-benefit assessment favors treatment with an oral quinolone agent rather than parenteral therapy with a nonquinolone agent. Qualifying infections could be located at any tissue site except the CNS. Examples of infections, many of which are hospital associated, include complicated UTI, bone or joint infection (including infection caused by *P. aeruginosa*), soft tissue infection, and lower respiratory tract infection. Because qualifying infections are uncommon, no prospective, randomized, controlled clinical trials of use of ciprofloxacin in children are available. Ciprofloxacin is also approved for the treatment of inhalational anthrax in children.

Fluoroquinolones achieve effective concentrations in the gastrointestinal tract and have an advantage over β-lactam antibiotics in that they also achieve high intracellular antibiotic concentrations, particularly effective in the treatment of *Salmonella* infections. Ciprofloxacin has been studied in children for shigellosis and salmonellosis and provides equivalent or superior rates of eradication compared with standard agents.[168,169]

With the high bioavailability of orally administered fluoroquinolones and activity against most gram-negative pathogens for immunocompromised children, selective use of these agents (with or without additional oral therapy for gram-positive pathogens) in low-risk children with fever and neutropenia is a promising area of clinical investigation.[170]

Levofloxacin

Levofloxacin was the first available agent in a series of newer fluoroquinolone agents with enhanced activity against gram-positive pathogens, including *S. pneumoniae* and MSSA. Levofloxacin has been clinically effective in treatment of upper and lower respiratory tract infections in adults,[171] with successfully completed clinical trials in children for acute otitis media and community-acquired pneumonia. No concerning safety issues were raised in adult or pediatric clinical programs. No joint-related toxicity was noted in children, with a sufficiently large number of subjects prospectively studied to detect a 1% adverse event rate. The most acknowledged clinical need for levofloxacin in children is for the treatment of unresponsive or recurrent otitis media due to pneumococci resistant to β-lactam and macrolide agents or treatment of these infections in a child allergic to standard antibiotics.[172] Use for therapy of serious infections is appropriate in situations for which no other class of active parenteral agent exists, or use as oral therapy of infections in situations for which only nonquinolone parenteral therapies exist.[165] Levofloxacin is approved for treatment of inhalational anthrax in children.

Moxifloxacin, Gemifloxacin

New generations of fluoroquinolones demonstrate increased activity against *S. pneumoniae* compared with earlier fluoroquinolones.[173] None have been approved for use in children.

Nitroimidazoles

Metronidazole

Metronidazole is a synthetic nitroimidazole antibiotic with a poorly defined mechanism of action despite decades of extensive use. Originally introduced for the treatment of *Trichomonas* infections (hence the original trade name, Flagyl), use in pediatrics has been most extensive for treatment of anaerobic infections, although metronidazole has never been approved by the FDA for use in children for this indication. Metronidazole is taken into cells by passive diffusion, and the nitro side chain on the imidazole ring is reduced intracellularly by the pyruvate-ferredoxin reductase complex into a toxic nitro radical that reacts with DNA, leading to DNA strand breaks, helix destabilization, and ultimately cell death in both dividing and nondividing cells. Metronidazole demonstrates concentration-dependent bactericidal activity. One of the major metabolites, a hydroxy derivative, retains significant antibiotic activity. Metronidazole is active against anaerobic bacteria and certain protozoa, including *Trichomonas, Entamoeba,* and *Giardia* (see Table 292.2).

In addition to direct bactericidal activity, metronidazole also appears to have direct effects on decreasing neutrophil generation of hydrogen peroxide and hydroxyl radicals, which may lead to decreased inflammation at the site of infection. Metronidazole also may inhibit lymphocyte transformation and granuloma formation. The clinical relevance of these observations is not known.

Although resistance to metronidazole is uncommon, a number of anaerobic bacteria, including some strains of *B. fragilis,* contain *nim* genes that code for an inactivating enzyme that may exist on both plasmids and within chromosomes. This enzyme effectively reduces the nitro group on metronidazole into a stable and inactive amine.[174–176]

Metronidazole is available in intravenous, oral tablet and capsule, and topical formulations. Although metronidazole has a very bitter taste and is not well tolerated when pulverized and placed in suspension, the absorption from the gastrointestinal tract is excellent, with >90% bioavailability. Although rectal administration yields approximately 70% to 80% bioavailability, this route of administration has never gained widespread acceptance for children. Metronidazole provides excellent therapeutic concentrations in a wide range of tissue sites, including CSF, in which concentrations are very close to those achieved in serum.[177–179] Although the serum elimination half-life is approximately 8 hours, early studies performed in adults for FDA approval used 6-hour dosing regimens, which remains the current FDA dosing recommendation on the package label. The observed half-life with oral administration appears to be longer than that found for intravenous administration, for unknown reasons. For most clinical situations, based on the pharmacodynamics of antibiotic exposure, dosing every 8 hours should be adequate. One metabolite of metronidazole displays significant antibacterial activity and has a more extended half-life, averaging 11 to 13 hours, providing another rationale for less frequent dosing.

Clinical use in pediatrics primarily is for the treatment of gram-negative anaerobic infections.[174,180] Given the excellent tissue penetration characteristics of metronidazole, activity against all susceptible anaerobes is achievable in most tissue sites. However, data from randomized, prospective clinical trials are not available for many sites of infection. Because many bowel and deep neck space infections involve gram-positive anaerobes as well as facultative and aerobic organisms, additional antibiotics may be necessary.

Metronidazole is bactericidal for *Bacteroides* spp. and has been used extensively as part of therapy of polymicrobial anaerobic/aerobic intra-abdominal infections, including complicated appendicitis, penetrating injury to the bowel, and colitis.[99] Other mixed infections include deep head and neck space infections (e.g., parapharyngeal abscesses, Ludwig angina) and necrotizing fasciitis or cellulitis (e.g., necrotizing synergistic fasciitis, Fournier gangrene, and omphalitis). *Clostridia* spp. also are susceptible to metronidazole, and deep tissue infections can be effectively treated. Some penicillin-susceptible anaerobic gram-positive cocci, however, are not susceptible to metronidazole.

Metronidazole, in combination with other antibiotics and proton pump inhibitors, is part of a treatment regimen for *H. pylori* –mediated ulcer disease.[181] In addition, there may be some benefit in the treatment of Crohn disease[182]; antibiotic and anti-inflammatory properties of the agent both may play a role.

Given the excellent penetration into CSF and bactericidal capacity, metronidazole is effective treatment for anaerobic organisms causing meningitis, ventriculitis (traumatic, postsurgical, or nosocomial), or brain abscess.[178] Prospective, comparative data to document efficacy for these indications are not available.

Metronidazole also can be used for certain female genital tract infections, including bacterial vaginosis, and as part of antimicrobial therapy of pelvic inflammatory disease.

A common use of metronidazole in children is for the treatment of *C. difficile* enterocolitis.[43] After the documented increases in vancomycin resistance of gastrointestinal tract flora with the use of oral vancomycin in adults for *C. difficile* colitis, metronidazole became the drug of choice in therapy for children as well as adults. Although clinical response rates comparing oral metronidazole therapy with oral vancomycin therapy for *C. difficile* infection have been equivalent in the past, currently there is concern regarding the efficacy of metronidazole in the treatment of *C. difficile* infection.[183]

Entamoeba histolytica trophozoites (but not cysts) are susceptible to metronidazole, allowing therapy for both intestinal and extraintestinal amebiasis, including amebic liver abscess.[184] Metronidazole is one of the drugs of choice for treatment of *Giardia* intestinal infections and is an alternative treatment for *Dientamoeba* infections.[184] Metronidazole remains effective therapy for *Trichomonas* infections for sexually active female and male adolescents.[185]

Sulfonamides (Single Agents or in Combination With Trimethoprim or Pyrimethamine)

Sulfisoxazole, Sulfamethoxazole, Sulfadiazine

The sulfonamide class was one of the first available antibiotics for human use, with striking clinical responses documented in 1937 in the treatment of erysipelas by sulfanilamide and its prodrug.[186,187] Unfortunately, because of widespread resistance in common bacterial pathogens, use of sulfonamides now is focused in a few areas of remaining effectiveness. For pathogens that remain susceptible to sulfonamides, either used alone or since 1968 when used in combination with trimethoprim, these agents have a long history of efficacy with reasonable safety. Sulfonamides now are used almost exclusively in combination with trimethoprim for the treatment or prophylaxis of bacterial infections.[188] Sulfadiazine currently is used in combination with pyrimethamine for the treatment of toxoplasmosis.

The sulfonamides are bacteriostatic by means of competitive inhibition of *para*-aminobenzoic acid, utilized by dihydropteroate synthase in the synthesis of dihydrofolic acid, a precursor of purine bases in the formation of nucleic acid. Bacteria that are required to synthesize folic acid are susceptible to this class of compounds.

Sulfa agents are well absorbed from the gastrointestinal tract and are, in general, metabolized by the liver and excreted by the kidney. Both sulfisoxazole and sulfamethoxazole are highly protein bound (70%–80%). As a result of sulfonamide binding to albumin, bilirubin may be displaced from its albumin-binding site, with subsequent bilirubin access to CNS tissue, causing kernicterus in ill, acidotic neonates with hyperbilirubinemia. No case of kernicterus has been documented in full-term, well-appearing infants. Despite FDA labeling cautions against the use of this class of agents in all infants younger than 2 months, use should be safe in nonacidotic term infants as early as the second week of life when physiologic neonatal jaundice is resolving.

Sulfonamides are responsible for one of the most serious drug-related adverse events: an intense immune-mediated separation of skin at the dermal-epidermal junction, separation of the respiratory and gastrointestinal tract mucosa from supporting connective tissue, or both. Variously called Stevens-Johnson syndrome, toxic epidermal necrolysis, or erythema multiforme major, the spectrum of reactions varies from a cutaneous erythematous, blistering rash to severe, extensive, life-threatening sloughing of skin and mucosa of the respiratory and gastrointestinal tract.[189,190] At the first sign of a skin reaction in a child receiving sulfa therapy, the child should be evaluated, the sulfonamide discontinued, and careful observation begun.

Trimethoprim Plus Sulfamethoxazole

Trimethoprim, available as a single agent but used far more commonly in children in combination with sulfamethoxazole (TMP-SMX), acts at the metabolic step following that inhibited by sulfonamides in the synthesis of purine bases.[188] TMP–SMX prevents the formation of tetrahydrofolic acid from dihydrofolic acid by binding to and reversibly inhibiting dihydrofolate reductase. The TMP-SMX combination blocks two consecutive steps in the synthesis of thymidine, providing both synergistic activity against most pathogens, and decreasing the risk for development of resistance to either the sulfa agent or trimethoprim. Trimethoprim displays bactericidal activity against bacteria, as does the combination.

Current clinical uses of TMP-SMX are limited in the treatment of UTI owing to increasing resistance of *E. coli,* except in regions where susceptibility is preserved. For children with urinary tract anomalies and significant reflux, TMP-SMX prophylaxis has been documented to decrease the number of recurrent UTIs.[191]

The rate of pneumococcal resistance to sulfa in most areas of the US is more than 40%, precluding it as first-line therapy of acute otitis media, sinusitis, or community-acquired pneumonia. Despite in vitro susceptibility of *S. pyogenes,* TMP-SMX is not recommended for treatment of streptococcal pharyngitis because host immune response to streptococci is not prevented reliably (which is required to prevent the development of acute rheumatic fever). However, treatment of skin infections caused by group A *Streptococcus* may still be effective, although current clinical outcome data have not been published recently.

TMP-SMX has been used increasingly for the treatment of CA-MRSA skin and skin structure infections, although prospective, controlled studies were never performed for skin and skin structure infections at the time of original antibiotic approval. New prospective, randomized studies now document the noninferiority of TMP-SMX compared with clindamycin in the treatment of uncomplicated skin and skin structure infections caused by CA-MRSA.[192] In vitro susceptibility of CA-MRSA to TMP-SMX is almost universal; data on comparable efficacy with clindamycin now support use for skin infections, but no data exist on therapy of CA-MRSA bone, joint, or pulmonary infections at this time.[192,193]

TMP-SMX is used for certain hospital-associated infections caused by MDR enteric gram-negative bacilli such as *Enterobacter* and *Klebsiella* spp. and *Stenotrophomonas maltophilia* (which often is susceptible). TMP-SMX generally is bactericidal, although not consistently for high-density inocula of gram-negative bacilli. TMP-SMX is considered safer than most other options (e.g., colistin, fluoroquinolones) in the treatment of MDR gram-negative infections and may provide adequate therapy for infections in most tissue sites, including meningitis, in situations for which no other well-evaluated therapeutic options exist.

Gastrointestinal infections caused by *Salmonella* and *Shigella* spp. and enteropathogenic strains of *E. coli* often were treated successfully with TMP-SMX in the past; however, the value of TMP–SMX has decreased as resistance in these gastrointestinal pathogens has increased.[83,155] The intracellular activity of TMP-SMX has been particularly advantageous in the treatment of susceptible strains of *Salmonella, Yersinia enterocolitica,* and *Vibrio cholera*. Susceptibility of enteric bacterial pathogens should be assessed before TMP-SMX is selected for therapy of serious infections. For parasitic infections of the gastrointestinal tract caused by *Cyclospora* spp. and *Cystoisospora* (formerly *Isospora*), TMP-SMX remains the treatment of choice.[194]

TMP-SMX remains effective therapy for brucellosis, nocardiosis (with exceptions), and some infections caused by the nontuberculous mycobacteria. Prophylaxis and treatment of *Pneumocystis* pneumonia in immunocompromised children remains highly effective.

Sulfadiazine Plus Pyrimethamine

The combination of sulfadiazine and pyrimethamine is active against a number of protozoa, including *Toxoplasma* and *Plasmodium*. Clinical use in children is limited primarily for congenital toxoplasmosis, with treatment starting as soon as physiologic jaundice has resolved, and for older children who have documented toxoplasmosis associated with immune deficiencies (primarily HIV related).

Miscellaneous

Nitrofurantoin

Nitrofurantoin is a unique antibiotic, characterized by a hydantoin ring with a nitro-substituted furanyl side chain that is metabolized within the bacteria to produce reactive compounds that are bactericidal. The mechanism of antibacterial activity is not well understood but presumably occurs by altering ribosomal proteins and other important intracellular structures. Both gram-positive bacteria (including staphylococci and streptococci) and gram-negative bacteria (*E. coli, Klebsiella* spp., and *Citrobacter* spp.) are susceptible. Mechanisms of resistance have not been well defined, but no cross-resistance occurs with other antibiotic classes. Recent data from the US on susceptibility of pediatric uropathogens document that, overall, resistance to nitrofurantoin across all pathogens and pediatric age groups is approximately 5% to 10%.[195]

Nitrofurantoin was approved by the FDA in 1953 for the treatment of uncomplicated UTIs. Nitrofurantoin is well absorbed orally and is rapidly cleared from the serum, producing subtherapeutic concentrations in serum, but bactericidal concentrations in urine. Currently available formulations include a rapidly absorbed monohydrate salt, a monohydrate salt in slow-release matrix, and crystalline nitrofurantoin that is also more slowly absorbed. Dosages should be decreased in children with any degree of renal insufficiency.

In clinical practice, nitrofurantoin has been used primarily for prophylaxis of UTI, although few prospective comparative data are available on which to base recommendations. Recent studies have defined the benefit of antimicrobial prophylaxis using TMP-SMX.[196–199] Serious pulmonary toxicities, both acute and chronic, were reported in the decade following availability of nitrofurantoin. Acute lung injury, thought to be immune mediated, and chronic fibrosis have been reported in adults during longterm therapy. The rate and severity of these multiple pulmonary toxicities have not been evaluated prospectively in children. However, no reports of pulmonary toxicity in young children receiving nitrofurantoin prophylaxis for UTI have been published, despite ongoing common use. In addition to pulmonary toxicity, hemolysis secondary to glucose-6-phosphate dehydrogenase deficiency has also been documented.

Methenamine

Methenamine hippurate is used exclusively for the prevention of UTI. Initially available in 1967 and approved by the FDA for patients 12 years or older, methenamine is a salt that ultimately exerts an antibacterial effect in the urine as it becomes converted into formaldehyde. This effect occurs when the urine pH is below 5.5. Formaldehyde has nonspecific bactericidal activity on both gram-positive and gram-negative bacteria. However, as the generation of formaldehyde is dependent on an acidic urinary pH, methenamine may not be active in situations in which a more alkaline pH is created by diet, or by urea-splitting bacteria in the urine, such as *Proteus* and *Pseudomonas.* A recent review of previously published data on clinical trials of methenamine prophylaxis, some of which were published as early as 1975, suggested efficacy for short-term use (<1 week) in adults with normal urinary tract anatomy.[200] Data collected in children in Finland from 1960 to 1974 suggest a benefit that is equivalent to, or superior to, sulfa and nitrofurantoin, although failures were not uncommon.[201] The clinical use of methenamine in children is not well defined currently because of lack of high-quality data on the safety and efficacy particularly for longterm prophylaxis.

Appendix 292.1 Dosage of Antibacterial Drugs for Infants, Older Children, and Adolescents

Drug Generic Name (Trade Name)	Administration Route	Dosage (per kg/day)[a]	Comments
AMINOGLYCOSIDES[b]			Dosage adjusted according to serum concentration(s).
Amikacin (Amikin)	IV, IM	15–22.5 mg divided into 1–3 doses	30–35 mg/kg/day for cystic fibrosis
Gentamicin (Garamycin)	IV, IM	3–7.5 mg divided into 1–3 doses	
Neomycin (numerous)	PO	50–100 mg divided into 4 doses (adults, 4–8 g/day; max., 12 g/day)	Minimally absorbed from GI tract
Streptomycin	IM, IV	20–40 mg once daily (adults, 1–2 g/day)	15–20 mg divided into 1–2 doses for non-MTB infections.
Tobramycin (Nebcin)	IV, IM	3–7.5 mg divided into 1–3 doses	7–10 mg/kg/day for cystic fibrosis
β-LACTAM AGENTS			
Monolactams			
Aztreonam (Azactam)	IV, IM	90–120 mg divided into 3–4 doses (adults, 3–6 g/day; max., 8 g/day)	
Carbapenems[c]			
Doripenem (Doribax)	IV	60 mg divided into 3 doses (adults, 1.5 g/day)	Max., 3–6 g/day by prolonged or continuous infusion for more serious *P. aeruginosa* infections
Ertapenem (Invanz)	IV, IM	30 mg divided into 2 doses; max., 1 g/day (children ≥13 yr and	

		adults, 1 g/day once daily)	
Imipenem-cilastatin (Primaxin)	IV, IM	60–100 mg divided into 4 doses (adults, 1–2 g/day; max., 4 g/day)	Seizures at high doses; not used for meningitis
Meropenem (Merrem)	IV	60 mg divided into 3 doses (adults, 3–6 g/day)	120 mg for meningitis or more serious *P. aeruginosa* infections; max., 6 g/day, may be given by prolonged or continuous infusion
Cephalosporins[c]			Methicillin-resistant staphylococci are resistant to all currently available cephalosporins, except ceftaroline
Cefaclor (Ceclor)	PO	20–40 mg divided into 2 doses (adults, 1–1.5 g/day)	
Cefadroxil (Duricef, Ultracef)	PO	30 mg divided into 2 doses (adults, 1–2 g/day)	
Cefazolin (Kefzol, Ancef)	IV, IM	50–100 mg divided into 3 doses (adults, 3–6 g/day; max., 12 g/day)	Up to 150 mg/kg/day for serious infections
Cefdinir (Omnicef)	PO	14 mg once daily; max., 600 mg/day	
Cefepime (Maxipime)	IV, IM	100–150 mg divided into 2–3 doses (adults, 2–6 g/day)	
Cefixime (Suprax)	PO	8 mg divided into 1 or 2 doses (adults, 400 mg/day)	
Cefotaxime (Claforan)	IV, IM	150–180 mg divided into 3 or 4 doses (adults, 3–6 g/day; max., 12 g/day)	200–300 mg divided into 4 doses for meningitis
Cefotetan (Cefotan)	IV, IM	60–100 mg divided into 2 doses (adults, 2–4 g/day; max., 6 g/day)	
Cefoxitin (Mefoxin)	IV, IM	80–160 mg divided into 3–4 doses (adults, 4–6 g/day; max., 12 g/day)	
Cefpodoxime proxetil (Vantin)	PO	10 mg divided into 2 doses (adults, 200–400 mg/day; max., 800 mg/day)	
Cefprozil (Cefzil)	PO	15–30 mg divided into 2 doses (adults, 0.5–1 g/day)	
Ceftaroline (Teflaro)	IV	Adults, 1.2 g/day divided into 2 doses	Investigational in children (see text)
Ceftazidime (Fortaz, Tazicef, Tazidime)	IV, IM	100–150 mg divided into 3 doses (adults, 3–6 g/day; max., 12	200–300 mg given by prolonged or continuous infusion for more serious

		g/day)	*Pseudomonas* infections.
Ceftazidime-avibactam (Avycaz)	IV	Adults, 7.5 g (6 g/1.5 g)/day divided into 3 doses	
Ceftibuten (Cedax)	PO	9 mg once daily (adults, 400 mg/day)	
Ceftriaxone (Rocephin)	IV, IM	50–100 mg divided into 1 or 2 doses (adults, 1–2 g/day; max., 4 g/day)	100 mg for meningitis and penicillin-resistant pneumococcal pneumonia
Ceftolozane-tazobactam (Zerbaxa)	IV	Adults, 4.5 g (3 g/1.5 g)/day divided into 3 doses	
Cefuroxime (Zinacef)	IV, IM	100–150 mg divided into 3 doses (adults, 2.25–4.5 g/day; max., 6 g/day)	Should not be used for meningitis
Cefuroxime axetil (Ceftin)	PO	20–30 mg divided into 2 doses, adults 0.5-1 g/day; max., 3 g/day	Up to 100 mg/kg/day for bone or joint infections
Cephalexin (Keflex)	PO	25–50 mg divided into 2 doses (adults, 1–2 g/day; max., 4 g/day)	75–100 mg divided into 3 or 4 doses for bone or joint infections, or for oral step-down therapy to replace parenteral therapy
PENICILLINS[c]			
Penicillin G and V			
Penicillin G, crystalline	IV, IM	100,000–300,000 units divided into 4–6 doses (adults, 8–24 million units/day)	Available as potassium or sodium salt
Penicillin G, procaine	IM	25,000–50,000 units divided into 1–2 doses (adults, 600,000–1.2 million units)	
Penicillin G, benzathine (Bicillin LA)	IM	50,000 units/kg once for infants <27 kg (60 lb) 300,000–600,000 units (not per kg) once ≥27 kg (60 lb) 900,000 units (not per kg) once (adult 1.2–2.4 million units once)	
Penicillin G benzathine-procaine (Bicillin CR)	IM	<14 kg (30 lb) 600,000 units (not per kg) once 14–27 kg (30–60 lb) 1,200,000 units (not per kg) once >27 kg (60 lb) 2,400,000 units (not per kg) once	
Penicillin V K	PO	25–50 mg divided into 3 or 4 doses (adults, 0.5–2 g/day)	75 mg divided into 4 doses for group A streptococcal pneumonia

Penicillinase-Resistant Penicillins			Methicillin-resistant staphylococci are resistant to all penicillins
Oxacillin (Bactocill)	IV, IM	100–200 mg divided into 4–6 doses (adults 4–6 g/day; max., 12 g/day)	
Nafcillin (Unipen, Nafcil)	IV, IM	100–200 mg divided into 4–6 doses (adults, 4–6 g/day; max., 12 g/day)	
Dicloxacillin (Dynapen)	PO	12.5–25 mg divided into 4 doses (adults, 0.5–1 g/day); max., 2 g/day	100 mg for bone or joint infections, or for oral step-down therapy to replace parenteral therapy
Aminopenicillins			
Amoxicillin (Amoxil)	PO	25–50 mg divided into 2–3 doses (adults, 0.75–3 g/day)	90 mg in 2 doses for AOM (higher doses for AOM due to certain pathogens) 80–100 mg in 3 doses for oral step-down therapy to replace parenteral therapy. Max., 4 g (not per kg)/day
Amoxicillin-clavulanate (Augmentin)	PO	14 : 1 formulation: 90 mg amoxicillin component divided into 2 doses 7 : 1 formulation: 25–45 mg amoxicillin component divided into 2 doses 4 : 1 formulation: 20–40 mg amoxicillin component divided into 3 doses	Max., 4 g (not per kg)/day
Ampicillin	IV, IM	100–200 mg divided into 4 doses (adults 4–12 g/day)	300–400 mg divided into 4–6 doses for meningitis
Ampicillin-sulbactam (Unasyn)	IV	100–200 mg ampicillin component divided into 4 doses (adults 4–8 g day)	
Ampicillin trihydrate (Principen)	PO	50–100 mg divided into 4 doses (adults 1–2 g/day)	
Broad-Spectrum Penicillins			
Piperacillin-tazobactam (Zosyn)	IV	240–300 mg piperacillin component divided into 3–4 doses (adults, 9–16 g piperacillin/day)	400–600 mg divided into 4–6 doses given by prolonged (3–4 hr) or continuous infusion for less susceptible organisms
Chloramphenicol sodium-succinate (Chloromycetin)	IV	50–100 mg divided into 4 doses (adults 2–4 g/day)	Dosage adjusted according to serum concentration(s)
FLUOROQUINOLONES			Arthropathy is a potential fluoroquinolone-class side effect in children

Ciprofloxacin (Cipro)	PO	20–40 mg divided into 2 doses; max. 1.5 g/day	
	IV	20–30 mg divided into 2–3 doses; max., 1.2 g/day	
Levofloxacin (Levaquin)	PO, IV	20 mg divided into 2 doses (children <5 yr); 10 mg once daily (children ≥5 yr) (adults, 500–750 mg/day)	See also Chapter 129 for use in *Bacillus anthracis* exposure, and Chapter 134 for use in MTB
Moxifloxacin (Avelox)	PO, IV	Adults, 400 mg once daily	10 mg/kg once daily for MTB
GLYCOPEPTIDES			
Vancomycin (Vancocin)	IV	45 mg divided into 3 doses 60–70 mg/kg/day for MRSA to achieve >400 mg · hr/L AUC	Dosage adjusted according to serum concentration(s)
	PO	40 mg divided into 4 doses (adults, 500 mg–2 g divided into 4 doses)	Poorly absorbed from GI tract
GLYCOLIPOPEPTIDES			
Dalbavancin (Dalvance)	IV	Adults, 1 g one time then 0.5 g in 1 wk	Investigational in children (see text)
Oritavancin (Orbactiv)	IV	Adults, 1200 mg once	
LINCOSAMIDES			
Clindamycin (Cleocin)	IM, IV	20–40 mg divided into 3 doses (adults, 900 mg–2.7 g/day; max., 4.8 g/day)	
	PO	10–30 mg divided into 3 doses (adults, 600 mg–1.8 g/day)	30–40 mg divided into 3–4 doses for AOM and CA-MRSA infection
LIPOPEPTIDES			
Daptomycin (Cubicin)	IV	4–6 mg once daily for children ≥12 yr; 7 mg once daily for 6–11 yr; 8–10 mg once daily for 2–5 yr	
MACROLIDES/AZALIDES			
Erythromycin (numerous)	PO	50 mg divided into 2–4 doses (adults, 1–2 g/day; max., 4 g/day)	Available as base, stearate, and ethyl succinate preparations
	IV	20 mg divided into 4 doses (adults, 1–2 g/day; max., 4 g/day)	Administer over at least 60 min
Clarithromycin (Biaxin)	PO	15 mg divided into 2 doses (adults, 0.5–1 g/day)	
Azithromycin (Zithromax)	PO	All doses once daily: AOM: 10 mg × 3 days; *or* 30 mg × 1 day; *or* 10 mg × 1 day, then 5 mg × 4 days	Max. doses: 10–12 mg/kg = 500 mg 5–6 mg/kg = 250 mg 30 mg/kg = 1.5 g 60 mg/kg ER susp = 2 g

		Pharyngitis: 12 mg × 5 days Sinusitis: 10 mg × 3 days; *or* 10 mg × 1 day, then 5 mg × 4 days Pneumonia: 10 mg × 1 day, then 5 mg × 4 days; *or* 60 mg × 1 day of ER susp if >6 mo of age Shigellosis: 12 mg × 1 day, then 6 mg × 4 days	
	IV	10 mg once daily; max., 500 mg	
MISCELLANEOUS			
Methenamine hippurate (Hiprex)	PO	1–2 g (not per kg) divided into 2 doses	
Methenamine mandelate (Mandelamine)	PO	<6 yr: 75 mg divided into 4 doses 6–12 yr: 2 g/day (not per kg) >12 yr: 4 g/day (not per kg)	
Nitrofurantoin (Furadantin)	PO	5–7 mg divided into 4 doses (adults, 200–400 mg/day)	1–2 mg once daily for UTI prophylaxis
NITROIMIDAZOLES			
Metronidazole (Flagyl)	PO	30–50 mg divided into 3 doses (adults, 0.75–2.25 g/day)	
	IV	22.5–40 mg divided into 3-4 doses (adults, 1–2 g/day; max., 4 g/day)	
OXAZOLIDINONES			
Linezolid (Zyvox)	PO, IV	<12 yr of age: 30 mg in 3 doses, 20 mg in 2 divided doses for uncomplicated skin infections. ≥12 yr and adults: 1200 mg per day (not per kg) in 2 doses	Myelosuppression increases with duration of therapy over 10 days
Tedizolid (Sivextro)	PO, IV	Adults, 200 mg once daily	
POLYMYXINS			
Colistin (as Colistimethate, Coly-Mycin M)	IV, IM	5–7 mg colistin base, divided into 3 doses	Reserved for multidrug-resistant gram-negative pathogens because of neurotoxicity and nephrotoxicity
Polymyxin B	IV	2.5–3 mg divided into 2 doses (adult dose same)	No maximum dose
RIFAMYCINS			
Rifampin (Rifadin)	PO, IV	10–20 mg divided	

		into 1–2 doses (adults, 600 mg/day)	
Rifaximin (Xifaxan)	PO	≥12 yr of age: 600 mg/day (not per kg) divided into 3 doses	
SULFONAMIDES			
Sulfadiazine	PO	120–150 mg divided into 4 doses (adults 4–6 g/day)	
Trimethoprim-sulfamethoxazole (TMP-SMX) (Bactrim, Septra)	IV, PO	8–12 mg TMP divided into 2 doses (adults, 160–320 mg TMP/day)	20 mg TMP divided into 4 doses for *Pneumocystis* pneumonia 2 mg TMP once daily for UTI prophylaxis 5 mg TMP divided into 2 doses for 3 consecutive days per week for *Pneumocystis* prophylaxis
STREPTOGRAMINS			
Quinupristin-dalfopristin (Synercid)	IV	15–22.5 mg divided into 2–3 doses (adult dose same)	
TETRACYCLINES			Tetracycline-class antibiotics stain unerupted teeth; use in children <8 yr of age if benefits exceed risks (see text)
Tetracycline (numerous)	PO	25–50 mg divided into 4 doses (adults, 1–2 g/day)	
Minocycline (Minocin)	PO, IV	4 mg divided into 2 doses (adults, 200 mg/day)	
Doxycycline	PO, IV	2–4 mg divided into 1–2 doses (adults, 100–200 mg/day)	
Demeclocycline (Declomycin)	PO	7-13 mg divided into 4 doses (adults, 600 mg/day)	

[a] Doses are listed as the number of dosing units (e.g., mg, µg) per kilogram **per day** along with the usual adult daily dose range ± an absolute maximal dose (not per kg per day, unless specified)

[b] Once-daily IV aminoglycoside dosing (amikacin 15–20 mg/kg; gentamicin/tobramycin 4.5–7.5 mg/kg) may provide equal efficacy with reduced toxicity and can be used as an alternative to multiple daily dosing.[202]

[c] In patients with a history of immediate hypersensitivity (anaphylaxis) to penicillin, other penicillins, cephalosporins, or carbapenems should not be used.

AOM, acute otitis media; AUC, area under the curve; CA, community associated; ER, extended release; GI, gastrointestinal; IV, intravenous; IM, intramuscular; MRSA, methicillin-resistant Staphylococcus aureus; MTB, Mycobacterium tuberculosis; PO, oral; TMP, trimethoprim; UTI, urinary tract infection.

Appendix 292.2 Drugs for Parasitic Infections

Drug	Route	Dosage (mg/kg per dose) and Frequency of Administration[a]			
		Body Weight ≤2 kg		Body Weight >2 kg	
		≤7 Days Old	8–28 Days Old	≤7 Days Old	8–28 Days Old
AMINOGLYCOSIDES[b,c,d]					
Amikacin	IV, IM	15 every 48 hr	15 every 24–48 hr	15 every 24 hr	15 every 12–24 hr
Gentamicin	IV, IM	5 every 48 hr	4–5 every 24–48 hr	4 every 24-36 hr	4 every 12–24 hr
Tobramycin	IV, IM	5 every 48 hr	4–5 every 24–48 hr	4 every 24-36 hr	4 every 12–24 hr
CARBAPENEMS					
Meropenem[e] *for meningitis*	IV	20 every 12 hr	20 every 8 hr[e]	20 every 8 hr	30 every 8 hr[e]
		40 every 8 hr	40 every 8 hr	40 every 8 hr	40 every 8 hr
CEPHALOSPORINS[b]					
Cefepime	IV, IM	30 every 12 hr	30 every 12 hr	50 every 12 hr[f]	50 every 12 hr[f]
Cefotaxime	IV, IM	50 every 12 hr	50 every 8 hr	50 every 12 hr	50 every 8 hr
Cefazolin	IV, IM	25 every 12 hr	25 every 8 hr	25 every 12 hr	25 every 8 hr
Ceftazidime	IV, IM	50 every 12 hr	50 every 8 hr	50 every 12 hr	50 every 8 hr
Ceftriaxone[g]	IV, IM	—	—	50 every 24 hr	50 every 24 hr
Cefuroxime	IV, IM	50 every 12 hr	50 every 8 hr	50 every 12 hr	50 every 8 hr
PENICILLINS					
Ampicillin[h]	IV, IM	50 every 12 hr	75 every 12 hr	50 every 8 hr	50 every 6 hr
for meningitis	IV	100 every 8 hr	100 every 8 hr	100 every 8 hr	75 every 6 hr
Nafcillin, oxacillin	IV, IM	25 every 12 hr	25 every 8 hr	25 every 8 hr	25 every 6 hr
for meningitis	IV	50 every 12 hr	50 every 8 hr	50 every 8 hr	50 every 6 hr
Penicillin G crystalline[i]	IV, IM	50,000 units every 12 hr	50,000 units every 8 hr	50,000 units every 12 hr	50,000 units every 8 hr
for meningitis	IV	100,000 units every 12 hr	100,000 units every 8 hr	100,000 units every 8 hr	100, 000 units every 6 hr
Penicillin G procaine	IM only	50,000 units every 24 hr	50,000 units every 24 hr	50,000 units every 24 hr	50,000 units every 24 hr
Piperacillin-tazobactam	IV	100 every 8 hr	100 every 8 hr	80 every 6 hr	80 every 6 hr
Ticarcillin-clavulanate	IV	75 every 12 hr	75 every 8 hr	75 every 12 hr	75 every 8 hr
OTHER AGENTS					
Azithromycin	PO, IV	10 every 24 h	10 every 24 hr	10 every 24 hr	10 every 24 hr
Aztreonam	IV, IM	30 every 12 hr	30 every 8 hr	30 every 8 hr	30 every 6 hr
Clindamycin	IV, IM, PO	5 every 8 hr	5 every 8 hr	7 every 8 hr	10 every 8 hr
Erythromycin	PO, IV	10 every 12 hr	10 every 8 hr	10 every 12 hr	10 every 8 hr
Linezolid	IV	10 every 12 hr	10 every 8 hr	10 every 8 hr	10 every 8 hr
Metronidazole[j]	IV	7.5 every 12 hr	7.5 every 12 hr	7.5 every 8 hr	10 every 8 hr
Vancomycin[d,k]	IV	15 every 24 hr	15–20 every 12–24 hr	20 every 24 hr	15 every 12–8 hr

[a] In milligrams (mg) unless otherwise specified. Dosages may need to be adjusted in neonates with severe renal impairment.

[b] May use the longer dosing interval (if given) in extremely low birth weight (<1000 g) neonates until 2 weeks of life.

[c] Dosages for aminoglycosides may differ from those recommended by the manufacturer and approved by the US Food and Drug Administration.

[d] Individualize dosage based on determination of serum concentrations.

[e] Adjust dosage after 14 days of age instead of after 7 days of age.

[f] 30 mg/kg if target pathogen MIC ≤4 mg/L.

[g] Neonates should not receive ceftriaxone intravenously if they are also receiving, or are expected to receive, intravenous calcium in any form, including parenteral nutrition. See Pediatrics 2009;123;e609. Cefotaxime is the preferred third-generation cephalosporin in neonates.

[h] 100 mg/kg/dose every 12 hours is also acceptable for empiric therapy of early-onset sepsis.

[i] Dosage applies to treatment of congenital syphilis and empiric therapy of early-onset sepsis. Some experts recommend 200–300,000 units/kg/day for other invasive infections.

[j] Begin with a 15-mg/kg loading dose.

[k] Dosing algorithm based on serum creatinine after DOL 5; if <0.7 then 15 mg/kg every 12 hr, if 0.7–0.9 then 20 mg/kg every 24 hr, if 1–1.2 then 15 mg/kg every 24 hr.

IV, intravenous; IM, intramuscular; PO, oral.

Reproduced from Bradley JS, Nelson JD (eds). Antiinfective therapy for newborns. In: Nelson's Pocketbook of Pediatric Antimicrobial Therapy, 23rd ed. Elk Grove Village, IL, American Academy of Pediatrics, 2017.

Antifungal Agents

Rachel L. Wattier, William J. Steinbach

Fungal infections generally can be divided into superficial infections that can affect children with normal immune systems and invasive infections that tend to occur primarily in children who are immunocompromised because of genetic defects, hematopoietic stem cell transplantation (HSCT), or solid-organ transplantation, or after a chemotherapeutic regimen used for childhood malignancies. Although conventional amphotericin B deoxycholate (AMB-D) was the drug of choice for many invasive fungal infections for years, now the many newer, safer, and more effective agents have largely relegated it to obsoletion. Lipid formulations of amphotericin B reduce the toxicity of conventional amphotericin B, and these agents have a role in the management of several specific diseases, such as mucormycosis. The newer triazoles—voriconazole, posaconazole, and isavuconazole—have expanded options for therapy against mold infections such as invasive aspergillosis. The echinocandins offer a class of antifungal therapy in which for the first time there is no cross-reactivity with a human substrate, leading to minimal toxicity.

There are important considerations when choosing antifungal agent, including the fungistatic versus fungicidal activity of certain antifungal classes against the various genera or even species of fungal pathogens and, most important, solid understanding of the differences in the pharmacokinetics of a drug in children compared with adults, which affect optimal dosing. Unfortunately, there have been few antifungal studies conducted in children. Consequently, most information for the pediatrician has been extrapolated from adult data. Through the efforts of dedicated clinicians and collaboration, pediatric indications and dosing strategies can be discovered that will directly benefit pediatric patients. This chapter provides a brief review of topical antifungal therapy and an overview of the current state of systemic antifungal therapy. The preferred treatment for each pathogen is covered in pathogen-specific chapters.

Superficial Infections

Among the therapeutic options available for treatment of fungal infections of the hair, skin, and nails, few have been tested in children, and fewer are approved for use in children younger than 13 years. Extrapolating data from adults treated for dermatomycoses to infants and children may not be justified. For example, manifestations of dermatomycoses vary with age, with tinea capitis seen almost exclusively in children.

The use of topical agents should be confined to infections of the epidermis or mucosal surfaces. The choice of treating superficial fungal infections with a topical or a systemic agent depends on the fungal pathogen, the site of infection, and the extent of the lesion. Systemic antifungal therapy almost always is used for tinea of the scalp, nails, palms, or soles; creams or solutions are preferred for fissured or intertriginous areas.

Topical Polyenes

Nystatin is a polyene antifungal agent named after New York State. It binds to ergosterol in the fungal cell membrane and causes changes in cell permeability and, eventually, cell lysis. Nystatin is useful for the treatment of mucosal and cutaneous infections caused by *Candida* spp. Nystatin is available as a suspension (100,000 U/mL), powder, cream, or ointment (100,000 U/g); a lozenge (200,000 U) to be dissolved in the mouth; an oral tablet (500,000 U); and a vaginal tablet (100,000 U). Oral forms are administered 4 or more times daily and are well tolerated because there is no significant systemic absorption, although large oral doses of the suspension can cause nausea. Nystatin is not effective against the dermatophytes.

Topical Azoles

The azole class (divided into imidazoles and triazoles based on chemical structure) inhibits ergosterol synthesis in the fungal cell membrane. Clotrimazole is an imidazole with broad-spectrum activity against *Candida* spp. and the dermatophytes *Trichophyton tonsurans, Trichophyton rubrum, Trichophyton mentagrophytes, Epidermophyton floccosum,* and *Microsporum canis* (Table 293.1). Clotrimazole also is effective against *Malassezia furfur,* the cause of tinea versicolor. Clotrimazole is one of the few topical antifungal agents studied in children. The 1% cream, lotion, and solution are available over the counter for the treatment of tinea pedis, tinea cruris, and tinea corporis. High concentrations of clotrimazole are achieved topically, but systemic absorption is negligible. Topical application generally is well tolerated but can cause local irritation or urticaria. Clotrimazole is available coformulated with 0.05% betamethasone, and this combination appears to foster more rapid healing of lesions in adults. However, this combination cream is not recommended for use in children because of the potential for systemic absorption of the corticosteroid.

TABLE 293.1

Categories and Activities of Antifungal Agents Against Dermatomycoses

Agent	Category	Trade Name	Activity Against			
			Candida Species	*Trichophyton tonsurans*	Other Dermatophytes	*Malass furfur*
Nystatin	Topical polyene	Mycostatin	+	–	–	–
Clotrimazole	Imidazole	Lotrimin	+	+	+	+
Miconazole	Imidazole	Desenex	+	+	+	+
Ketoconazole	Imidazole	Nizoral	+	+/–	+	+/–
Oxiconazole	Imidazole	Oxistat	+	+	+	+
Terbinafine	Allylamine	Lamisil	–	+/–	+	+/–
Naftifine	Allylamine	Naftin	–	+/–	+	–
Butenafine	Benzylamine	Mentax	–	+	+	+/–
Ciclopirox	Hydroxypyridone	Ciclodan	+	+	+	+
Griseofulvin	*Penicillium* derivative	Fulvicin	–	+	+	–

+, Activity; –, no activity; +/-, variable activity.

Miconazole is an imidazole available over the counter as a 2% cream. Its spectrum of activity is identical to that of clotrimazole, and in clinical trials it has demonstrated equivalent efficacy. Its efficacy in the treatment of superficial *Candida* infections is better than that of nystatin, and it has the advantage of once-a-day application. Local side effects, such as those seen with clotrimazole, can occur, and miconazole should be used sparingly in intertriginous areas to avoid maceration of the skin.

Ketoconazole is an imidazole available as a 2% cream. Ketoconazole is effective therapy for dermatomycoses caused by *Candida* spp., *T. rubrum, T. mentagrophytes, E. floccosum,* and *M. furfur.* Although it has in vitro activity against *T. tonsurans* and *Microsporum,* the clinical relevance of these data to efficacy is not known. Ketoconazole applied topically is not absorbed systemically but can cause local irritation. Ketoconazole also is available as an oral tablet formulation, but its use as systemic therapy is associated with life-threatening hepatotoxicity and adrenal insufficiency, and the United States Food and Drug Administration (FDA) specifically recommends *against* use of this oral formulation as first-line therapy for any fungal infection.

Econazole is an imidazole nearly identical in structure to miconazole. Its activity and adverse reactions are similar. Published studies demonstrate cure rates for dermatomycoses similar to those of other topical imidazoles, but comparative studies have not been performed, and econazole has no clear advantage over other topical azoles.

Additional topical azoles include oxiconazole, terconazole, sertaconazole, and luliconazole. Oxiconazole is an imidazole that is approved for the treatment of tinea pedis, tinea cruris, tinea corporis, and tinea versicolor. Terconazole is an imidazole formulated only for vaginal use in the treatment of *Candida* vaginitis. Sertaconazole is an imidazole approved for treatment of tinea pedis. Luliconazole is an imidazole approved for tinea pedis, tinea cruris, and tinea corporis. Pediatric experience with these newer agents is limited.

Griseofulvin

Griseofulvin is approved by the FDA for tinea capitis (daily for 6 to 12 weeks), a condition almost uniformly refractory to treatment with topical agents and therefore requiring oral antifungal therapy.

Griseofulvin impairs fungal mitosis by interfering with microtubule formation, and it deposits in keratin precursor cells, binding to newly formed keratin and thereby preventing fungal invasion. Griseofulvin is fungistatic in vivo against *Trichophyton* spp., *E. floccosum*, and *Microsporum* and is not active against *Candida* or *M. furfur*. Absorption of griseofulvin from the gastrointestinal tract varies considerably but is increased by decreasing the size of the crystals (microcrystalline and ultracrystalline formulations are available, but the ultracrystalline formulation is not available as a suspension) and administering the drug with a meal high in fat content. Historically, the dose of griseofulvin for children was 10 to 15 mg/kg/day, but because of increasing resistance, many experts now recommend 20 to 25 mg/kg/day.

Griseofulvin has a longstanding history of safety and efficacy in children. Because it is metabolized by the liver, adjustment in dosage is not necessary in patients with renal impairment. Side effects are infrequent but include hypersensitivity rash, urticaria, nausea, vomiting, diarrhea, headache, fatigue, proteinuria, and leukopenia. Elevated levels of serum hepatic enzymes can occur, but laboratory monitoring is generally not indicated in healthy children treated with durations of 8 weeks or less. Periodic monitoring of complete blood counts and of hepatic and renal function is recommended if therapy is continued for ≥8 weeks. Griseofulvin can decrease the effects of oral anticoagulant and contraceptive agents. Its antifungal effect can be decreased by the concurrent administration of phenobarbital.

Squalene Epoxidase Inhibitors

The allylamines terbinafine and naftifine act by inhibiting squalene epoxidase, an enzyme in the pathway leading to the synthesis of ergosterol in the fungal cell membrane. Terbinafine is available as both a topical preparation and an oral tablet. Topical terbinafine is at least as effective as other topical antifungal agents. Its main advantage is that favorable clinical responses can be achieved with short durations of therapy, with high cure rates for tinea pedis observed after even a single application.[1] The oral tablet has high absorption (>70%) and a long half-life (approximately 36 hours), penetrates keratinized tissues, and maintains concentrations higher in skin and nails than serum for 1 week after stopping treatment. Unlike griseofulvin, no liquid formulation is available. Both griseofulvin and terbinafine are active against the common dermatophytes and have proven efficacy in the treatment of dermatomycoses in adults. A meta-analysis of randomized controlled trials comparing terbinafine with griseofulvin for the treatment of tinea capitis concluded that 2 to 4 weeks of terbinafine therapy is at least as effective as 6 to 8 weeks of griseofulvin, with no differences in tolerability or adverse effects and overall cost savings with the 4-week therapy.[2] More recent meta-analyses have suggested superiority of terbinafine for tinea capitis caused by *Trichophyton* spp. and of griseofulvin for tinea capitis caused by *Microsporum* spp.[3,4] Children require higher doses of terbinafine to achieve exposure similar to that of adults. A clinical trial conducted in children with tinea capitis caused by the recalcitrant species *M. canis* demonstrated higher cure rates in those who received higher doses (7–12.5 mg/kg/day) of terbinafine.[5]

Butenafine is a benzylamine with a mechanism of action similar to that of the allylamine class of antifungal agents. Butenafine is indicated for the topical treatment of tinea pedis, tinea corporis, and tinea cruris.

Other Topical Agents

Undecylenic acid is an unsaturated fatty acid antifungal agent available as an ointment, powder, or liquid. Its therapeutic efficacy was first recognized in the 1940s in treating superficial fungal diseases affecting military troops. However, it has little efficacy compared with newer agents. Tolnaftate has similar activity against dermatophytes, with cure rates of 60% to 90% for superficial infections.[6] Tinea capitis and tinea unguinum frequently are refractory, probably because of poor penetration of tolnaftate into involved areas. The advantages of these compounds are that they are safe, inexpensive, and rarely cause local irritation.

Gentian violet is a triphenylmethane dye mixture that is fungicidal against *Candida* spp. through an unknown mechanism. It has been used as a traditional remedy for mucocutaneous candidiasis through topical application of a dilute mixture and has gained favor recently as a treatment for refractory mucocutaneous candidiasis, particularly in resource-poor areas. Its disadvantages are the lack of a standard pharmaceutical grade formulation, mucosal irritation, and surface staining.

Ciclopirox is a hydroxypyrimidine antifungal that acts by chelating iron and thereby inhibiting iron-dependent fungal enzymes. It is active against all of the clinically relevant dermatophytes, *Candida* spp., and *M. furfur* and is available in multiple topical formulations to treat infections of the skin and as a nail lacquer to treat onychomycosis.

Invasive Infections

The armamentarium of antifungal choices for invasive fungal infections has increased substantially in recent years (Tables 293.2 and 293.3). Although choices once were limited and often ineffective, several better tolerated and more effective agents are now available. Clinicians must consider many factors when selecting therapy, including the disease state, causative organism, antifungal resistance patterns, and host factors such as concurrent medications, hepatic function, and prior exposure to antifungal therapy. Currently licensed systemic antifungal agents include amphotericin B and its lipid derivatives; 5-fluorocytosine; the triazoles, including fluconazole, itraconazole, voriconazole, posaconazole, and isavuconazole; and the echinocandins, including caspofungin, micafungin, and anidulafungin.

TABLE 293.3

Preferred Pediatric Dosing of Approved Systemic Antifungal Agents

Drug Class	Antifungal Drug[a]	Preferred Adult Dosing	Preferred Pediatric Dosing	Pediatric Dosing Comments
Polyene	Amphotericin B deoxycholate (AMB-D; Fungizone)	1–1.5 mg/kg/day	1–1.5 mg/kg/day	Children generally tolerate higher doses than do adults
	Amphotericin B Lipid Complex (ABLC; Abelcet)[a]	5 mg/kg/day	5 mg/kg/day	
	Liposomal Amphotericin B[a] (L-AmB; AmBisome)	5 mg/kg/day	5 mg/kg/day	
Pyrimidine analogue	5-Fluorocytosine (Ancoban)	100 mg/kg/day divided every 6 hr	100 mg/kg/day divided every 6 hr	Use caution with large oral volume for neonates
Triazole	Fluconazole (Diflucan)	200–800 mg/day; 6–12 mg/kg/day	6–12 mg/kg/day	Dose higher in children due to higher clearance; neonates require further special dosing. Use 12 mg/kg/day dosage for invasive candidiasis.
	Itraconazole (Sporanox)	200–400 mg/day	2.5–5 mg/kg/dose twice daily	Dosing twice daily preferred in children, and if dose exceeds 200 mg/day
	Voriconazole (VFend)	Load: 6 mg/kg/dose	<12 yr: Load: 9	Young children require higher doses due to higher clearance. Oral bioavailability lower in

		twice daily × 1 day Maintenance: 4 mg/kg/dose twice daily	mg/kg/dose twice daily × 1 day Maintenance: 8 mg/kg/dose twice daily ≥ 12 yr: Same as adult dosing	children than in adults. Therapeutic drug monitoring is strongly recommended
	Posaconazole (Noxafil)	Suspension: 200 mg every 6 hr or 400 mg twice daily Tablet (delayed release): 300 mg twice daily × 1 day, then 300 mg daily IV: 300 mg twice daily × 1 day, then 300 mg daily	<13 yr: Suspension: 4 mg/kg/dose 3 times daily ≥13 yr: Same as adult dosing	Data on pediatric dosing has not been fully studied; the suggested dose for children <13 yr is based on a prophylaxis study. Oral absorption of suspension formulation is improved when dose is taken with a fatty meal
Echinocandin	Caspofungin (Cancidas)	Load: 70 mg daily × 1 day Maintenance: 50 mg daily	Load: 70 mg/m^2 daily × 1 day Maintenance: 50 mg/m^2 daily	Dosing for hepatic insufficiency in children is 35 mg/m^2 daily, similar to the adult decrease to 35 mg daily
	Micafungin (Mycamine)	100–150 mg/day	2–10 mg/kg/day	Very dependent on age of child; neonates require far higher doses than do older children
	Anidulafungin (Eraxis)	Load: 200 mg daily × 1 day Maintenance: 100 mg daily	Load: 3 mg/kg/day × 1 day Maintenance: 1.5 mg/kg/day	

[a] ABLC is recommended officially at 5 mg/kg/day, ABCD at 3–5 mg/kg/day, and L-AmB at 3–5 mg/kg/day; IV, intravenous. Most clinical data have been obtained with the use of these preparations at 5 mg/kg/day, and most clinicians use and prefer this higher dosing. (Note: ABCD is no longer available in the US.)

Polyenes

Amphotericin B

Mechanism of Action.

The oldest antifungal class is the polyene macrolides—

amphotericin B and nystatin. After initial approval for use in 1958, AMB-D remained for years the gold standard for the therapy of many invasive fungal infections, as well as the comparator agent for newer antifungal agents. Amphotericin B binds to ergosterol, the major sterol found in fungal cell membranes, creating transmembrane channels resulting in an increased permeability to monovalent cations. Fungicidal activity is believed to be caused by leakage of essential nutrients from the fungal cell. Despite its broad spectrum of activity, there are notable intrinsically resistant organisms, such as *Aspergillus terreus*.[7]

Pharmacology and Toxicities.

Amphotericin B is given as an intravenous (IV) formulation, with once-daily dosing because of its prolonged half-life. Cerebrospinal fluid (CSF) and intraocular concentrations are <5% of serum concentrations. However, amphotericin B and its derivatives have been used successfully to treat invasive fungal infections of the central nervous system (CNS), often in combination with a second agent. The primary route of elimination is unknown. Although a small portion of elimination occurs through the kidneys and biliary tract, serum levels are not affected by renal or hepatic impairment. Although not needed to account for differences in drug exposure, dose adjustment may be considered in patients with renal impairment with the goal of reducing further nephrotoxicity and likely best through moving to alternate-day dosing. Amphotericin B is highly protein bound and poorly dialyzable. It has few direct drug interactions, although additive nephrotoxicity can be seen when it is used concurrently with other nephrotoxic drugs.

The fungicidal activity of amphotericin B is concentration dependent, increasing directly with the amount of drug attained at the site of infection, but beginning to plateau at concentrations 4 to 10 times higher than the minimal inhibitory concentration (MIC) of the organism.[8,9] Amphotericin B also has a prolonged post-antifungal effect, allowing antifungal activity to persist even after the concentration of drug falls below the MIC of the organism.[10] Despite in vitro data suggesting a benefit of escalating drug concentrations, there is no conclusive clinical evidence that doses higher than 1 mg/kg/day of AMB-D are necessary for successful therapy.[11]

The major dose-limiting toxicity of conventional amphotericin B is nephrotoxicity, which is related to binding of cholesterol in distal renal tubule cell membranes, where the drug concentrates. In addition, amphotericin B stimulates release of proinflammatory cytokines from mononuclear cells, accounting for infusion-related toxicities including fever, chills, and headache. Several lipid formulations of amphotericin B have been developed to reduce these toxicities. The FDA approved amphotericin B lipid complex (ABLC) in 1995, amphotericin B cholesteryl sulfate complex (amphotericin B colloidal dispersion, ABCD) in 1996, and liposomal amphotericin B (L-AmB) in 1997.

Although the exact mechanism by which lipid amphotericin B formulations reduce toxicity is unknown, several potential mechanisms have been proposed. These include stabilization of the drug in a self-associated state so that it cannot interact with the cholesterol of human cellular membranes, and preferential binding to serum high-density lipoproteins, leading to slower release of amphotericin B to the kidney compared with conventional amphotericin B that is bound to low density lipoproteins.[12] In addition, compared with AMB-D, lipid amphotericin B formulations have greater distribution to the reticuloendothelial system and lower distribution to the kidney (as another potential reason for reduced toxicity).[13,14]

Clinical studies show favorable tolerability of therapy with lipid amphotericin B formulations, both in adults and children. A multicenter, maximal-tolerated-dose study of L-AmB in adults using doses from 7.5 to 15 mg/kg/day found a nonlinear plasma pharmacokinetic profile with a maximal concentration at 10 mg/kg/day and no demonstrable dose-limiting nephrotoxicity or infusion-related toxicity.[15] A randomized clinical trial comparing L-AmB at a standard dose of 3 mg/kg/day and a higher dose of 10 mg/kg/day failed to show any improvement in efficacy and yielded more nephrotoxicity with the higher dose.[16] Currently, standard doses of 3 to 5 mg/kg/day L-AmB are recommended.

Although amphotericin B–related nephrotoxicity generally is less severe in infants and children than adults, likely because of more rapid clearance of the drug, comparatively lower rates of nephrotoxicity have been observed in children and neonates receiving lipid formulations.[17–19] A pharmacokinetic study of L-

AmB conducted in 39 children observed no dose-related trends in adverse events and identified a maximally tolerated dose of 10 mg/kg/day.[20] These results are similar to those observed in adults.[15]

Although there are anecdotal reports of using conventional amphotericin B in numerous instillation or irrigation methods (including intrathecal, intrapleural, or intra-articular instillation or bladder irrigation), there are no controlled data to support these uses. Often the drug irritates the surrounding tissue, potentially creating more side effects than clinical benefit. Inhaled amphotericin B has been used successfully as antifungal prophylaxis in lung transplant recipients but has not been shown to be effective as adjunctive therapy in a broader patient population. Intravitreal injection of amphotericin B has been used to treat fungal endophthalmitis.

Clinical Experience and Pediatric Data.

The optimal duration of amphotericin B therapy is unknown but likely is dependent on the underlying disease, extent of fungal infection, and recovery of host immune function. Several pathogen-specific guidelines have been published and include recommendations for dose and duration of amphotericin B–based treatment regimens.

Although mortality was slightly lower in patients treated with L-AmB compared with conventional AmB in one study with a small number of patients,[21] and a lower rate of breakthrough fungal infections occurred in another study of patients treated empirically for febrile neutropenia,[22] other comparative studies have shown similar clinical outcomes for patients treated with amphotericin B lipid formulation and those treated with conventional amphotericin B.[23] A study of 56 infants with candidiasis, including 52 preterm infants, showed no differences in mortality or time to resolution of candidemia between neonates receiving conventional AMB-D (n = 34), L-AmB (n = 6), or ABCD (n = 16).[24] The decision to prescribe a lipid formulation of amphotericin B should be based on the potential for reduced nephrotoxicity or infusion-related toxicity rather than anticipated therapeutic benefit. In US children's hospitals, utilization of lipid formulations of amphotericin B has increased since their introduction, such that they are now more commonly used than conventional AMB-D.[25]

Evidence supporting the use of amphotericin B and its lipid formulations in children is derived largely from extended clinical experience and nonrandomized studies demonstrating tolerability and efficacy when used for treatment of invasive fungal infections.[17–20] Although newer agents with improved tolerability and efficacy have emerged for conditions such as invasive aspergillosis, AMB-D and its lipid formulations remain important in the therapy of cryptococcal meningitis, severe manifestations of endemic mycoses, mucormycosis, and neonatal candidiasis, and for patients with resistant fungal pathogens or contraindications to other agents.

Pyrimidine Analogues

5-Fluorocytosine

Mechanism of Action.

5-Fluorocytosine (5-FC) is a fluorinated analogue of cytosine that has antimycotic activity resulting from the rapid conversion of 5-FC into 5-fluorouracil (5-FU) within susceptible fungal cells.[26] 5-FU inhibits fungal protein synthesis following incorporation into fungal RNA in place of uridylic acid or through inhibition of thymidylate synthetase, thus inhibiting fungal DNA synthesis. 5-FC has little inherent activity against molds, and most reports describe clinical failure with monotherapy against yeast infections. Antifungal resistance develops quickly on 5-FC monotherapy, so the drug should be used only in combination with other agents. 5-FC is thought to enhance the antifungal activity of amphotericin B, especially in anatomic sites where amphotericin B penetration is poor, such as CSF, heart valves, and the ocular vitreous fluid.[27] One explanation for the synergy detected with amphotericin B and 5-FC is that the membrane-permeabilizing effects of low concentrations of amphotericin B facilitate penetration of 5-FC into the cell interior.[28]

Pharmacology and Toxicities.

5-FC is well absorbed after oral administration.[26] It is small, highly water soluble, and not highly protein bound, so it distributes widely, attaining therapeutic concentrations in most body sites, including CSF, vitreous and peritoneal fluids, and inflamed joints.[26] Because it often is technically difficult to treat neonates with 5-FC because of the large volume required when using the oral formulation and the lack of an IV formulation available in the US, 5-FC is no longer recommended for treatment of neonatal candidiasis.

5-FC toxicity appears to be due to its conversion to 5-FU, with reports of serum 5-FU concentrations in the range found after chemotherapeutic doses.[29] 5-FC can exacerbate myelosuppression in patients with neutropenia, and trough serum concentrations of ≥100 µg/mL are associated with bone marrow aplasia. Therefore, 5-FC serum concentrations should be monitored closely and levels maintained at approximately 40 to 80 µg/mL. In a multicenter trial of 194 patients who received AMB-D plus 5-FC for cryptococcal meningitis, hematologic toxicity appeared in the first 2 weeks of therapy in 56% of patients and in the first 4 weeks of therapy in 87%.[30] Neonates have slower clearance of 5-FC and are more susceptible to having serum levels exceeding the recommended therapeutic range.[31] Clearance is through the kidneys, and the interval between doses should be extended in the setting of renal dysfunction.

Clinical Experience and Pediatric Data.

A pivotal trial showed that the combination of AMB-D plus 5-FC was more effective than AMB-D alone in the treatment of cryptococcal meningitis.[32] A subsequent multicenter study of 194 patients with cryptococcal meningitis concluded that 4 weeks of AMB-D plus 5-FC was adequate for immunocompetent patients without neurologic complications such as hydrocephalus. However, among immunocompromised patients, 6 weeks of combination therapy resulted in fewer relapses.[33] AMB-D in combination with 5-FC currently is recommended as initial therapy for cryptococcal meningitis.[34] These two agents also are suggested for use in patients with candidal meningitis or endocarditis.[35] Although there are many historic reports of 5-FC combined with AMB-D to penetrate difficult sites of infection such as the joints, eyes, or CNS, this use for 5-FC has diminished with the advent of newer antifungal agents.

There are limited data regarding the use of 5-FC in children. One review of 17 cases of candidal meningitis (including 11 patients younger than 12 months of age) noted improvement in 15 patients treated with AMB-D plus 5-FC.[36]

Azoles

The azole antifungal agents are heterocyclic synthetic compounds that inhibit the fungal cytochrome $P450_{14DM}$ (lanosterol 14α-demethylase), which catalyzes a late step in ergosterol biosynthesis. The drugs bind through a nitrogen group in their 5-membered azole ring to the heme group in the target protein and block demethylation of the C14 of lanosterol, leading to substitution of methylated sterols in the membrane and depletion of ergosterol. The result is an accumulation of precursors leading to abnormal fungal membrane permeability, membrane-bound enzyme activity, and coordination of chitin synthesis.[37,38] The fungicidal activity of the azoles is organism dependent, with most agents exhibiting fungistatic activity against *Candida* spp.; itraconazole and voriconazole have fungicidal activity against *Aspergillus*.[39]

The azoles are subdivided into imidazoles and triazoles on the basis of the number of nitrogens in the azole ring, with the structural differences resulting in different binding affinities of the azole pharmacophore for the cytochrome P450 (CYP) enzyme system. With the exception of ketoconazole, use of imidazoles is limited to superficial mycoses, and none, including ketoconazole, has activity against molds such as *Aspergillus*. In 2013, the FDA issued a recommendation that, owing to its association with life-threatening hepatotoxicity and adrenal insufficiency, oral ketoconazole should not be used as first-line therapy for any fungal infection and should be used only for treatment of endemic mycoses if alternative antifungal therapies are lacking.

Fluconazole

Pharmacology and Toxicities.

Fluconazole is a triazole that was approved by the FDA in 1990 for therapy of cryptococcosis and *Candida* infections. Fluconazole also has activity against endemic mycoses, but no activity against the opportunistic molds. Available in oral and IV formulations, oral fluconazole is >90% bioavailable. Unchanged drug is predominantly cleared by the kidneys; metabolism accounts for only a minor proportion of fluconazole clearance.[40] Dose adjustment is indicated in the setting of impaired renal function. Fluconazole distributes into tissues and fluids rapidly, probably owing to its relatively low lipophilicity and limited binding to plasma proteins. Drug concentrations in CSF and vitreous fluid are approximately 80% of those found in blood.[41] Concentrations of fluconazole are 10- to 20-fold higher in the urine than blood, making fluconazole particularly appropriate for the therapy of fungal urinary tract infections.

The pharmacokinetics of fluconazole differ between adults and children. Except in neonates, fluconazole clearance is more rapid in children than adults.[40] The mean plasma half-life is approximately 20 hours in children, compared with 30 hours in adults. Therefore, to achieve comparable drug exposure, the daily fluconazole dose needs to be approximately doubled, to 6 to 12 mg/kg/day, for children older than 3 months.

The volume of distribution of fluconazole is greater and more variable in neonates than in older infants and children. Clearance of fluconazole is lower in neonates than in adults and older children and, in a population pharmacokinetic study, was found to vary based on weight, gestational age, and postanatal age.[42] Therefore, neonates should be treated with a higher dose of fluconazole to compensate for increased volume of distribution, but less frequent dosing because of slower clearance. Because of the long half-life of fluconazole in neonates, patients require at least 8 days to reach steady-state.[43] A pilot study of a 25-mg/kg loading dose of fluconazole in neonates demonstrated faster attainment of target drug exposure without demonstrable adverse effects.[44]

Fluconazole exhibits concentration-independent activity against fully susceptible *Candida* isolates but concentration-dependent activity against dose-dependent (less) susceptible isolates.[10] The ratio of fluconazole dose to MIC has been shown to correlate with clinical response in adults with invasive candidiasis; a target ratio of at least 400 is recommended for most patients, with a ratio of at least 800 recommended as a target for critically ill patients.[45] In children, this target exposure is more likely to be achieved at doses of 12 mg/kg daily. Side effects of fluconazole are uncommon. In a study of 24 immunocompromised children, elevated serum hepatic transaminases were observed in only 2 cases.[46] Another review of 562 children confirmed that pediatric results mirror the excellent safety profile of adults. The most common side effects were gastrointestinal upset (7.7%) and skin rash (1.2%).[47] Through interaction with the CYP enzyme system, fluconazole can increase blood levels of various medications, including cyclosporine and tacrolimus, albeit to a lesser degree than mold-active triazoles.

Clinical Experience and Pediatric Data.

In one clinical trial of 206 nonneutropenic adults with invasive candidiasis, the rate of successful therapy with 0.5 to 0.6 mg/kg/day of AMB-D (79%) was similar to that of 400 mg/day of fluconazole (70%).[48] Another multicenter trial of 219 nonneutropenic adults with invasive candidiasis found that those treated with a combination of fluconazole plus AMB-D ($n = 112$) showed no difference in time to blood sterilization compared with those treated with fluconazole alone ($n = 107$).[49] Although a secondary analysis suggested that combination therapy was superior in efficacy to fluconazole alone, the difference in favorable outcome was small (69% vs. 56%; $P = 0.043$). Currently, there is no definitive evidence supporting the benefit of this combination therapy to treat invasive candidiasis.

Early, uncontrolled studies demonstrated favorable outcomes (clinical cure rates ranging from 83% to 97%) when fluconazole was used for treatment of invasive fungal infections in infants and children who were unresponsive or intolerant to standard antifungal therapy.[50] A subsequent prospective randomized study that compared fluconazole with AMB-D in 24 infants with candidemia noted increased convenience of therapy with fluconazole and a slight, but not statistically significant, survival benefit among those treated with fluconazole (67%) versus (55%), respectively.[51] Of note, early studies evaluating fluconazole for treatment of invasive fungal infections generally studied lower doses than those currently recommended to achieve adequate drug exposure.

Fluconazole also has been evaluated for antifungal prophylaxis. Randomized, placebo-controlled clinical trials have demonstrated that prophylactic fluconazole following allogeneic bone marrow transplantation results in lower rates of candidal infection and graft-versus-host disease.[52] Studies conducted in adult HSCT recipients demonstrated that 200 mg/day of fluconazole is comparable in efficacy to low-dose AMB-D and to fluconazole at a dose of 400 mg/day.[53,54] Randomized, placebo-controlled trials have shown that fluconazole prophylaxis reduces the incidence of fungal colonization and invasive candidiasis among very low birth weight neonates in neonatal intensive care units with a high burden (≥15%) of candidiasis.[55–57] A randomized controlled trial conducted in 361 extremely low birth weight neonates from neonatal intensive care units with a lower incidence of candidiasis did not show a significant benefit of fluconazole prophylaxis for reduction in the composite outcome of mortality or invasive candidiasis.[58]

Itraconazole

Pharmacology and Toxicities.

Itraconazole has been available for clinical use since 1990. Compared with fluconazole, itraconazole has an expanded spectrum of activity, including *Aspergillus*, but it has erratic bioavailability and is more prone to drug-drug interactions. In the US, itraconazole is only available in oral formulations (capsule and solution). Oral bioavailability is highly variable and is greater for the solution formulation than the capsule. Absorption of the capsule formulation is affected by gastric pH; acid-suppressant medications may decrease drug absorption, whereas acidic beverages may enhance absorption. Administration of the capsular formulation with food increases absorption, but the oral suspension is better absorbed on an empty stomach and is not affected by gastric pH. Itraconazole is highly protein bound, but unbound itraconazole distributes widely to tissues, including bone; it has relatively poor penetration of CSF and ocular fluid. Itraconazole is eliminated primarily through hepatic metabolism; there is no need for dosage adjustment in the presence of impaired renal function.[38]

Serum concentrations of itraconazole are much lower in children than in adults after administration of the oral solution. This is especially true in children younger than 5 years.[59] Therefore children usually need twice-daily dosing, whereas once-daily dosing is appropriate for adults. Because of the importance of effectively monitoring itraconazole concentrations, as well as its erratic absorption, clinicians should use caution when using itraconazole in children.

Itraconazole can be difficult to tolerate, with nausea and vomiting (due to the cyclodextrin vehicle) occurring in about 10% of subjects and elevated serum hepatic transaminases in 5%.[60] Rare cases of cardiomyopathy have been reported in adults, but no cases have been described in children. Itraconazole is a potent inhibitor of the CYP3A4 enzyme and therefore can result in important drug interactions. Prior or concurrent use of rifampin, phenytoin, carbamazepine, and phenobarbital should be avoided, and concomitant use with cyclophosphamide should be discouraged.[61] Drugs metabolized by the CYP3A4 pathway that normally have low bioavailability, extensive first-pass metabolism, or narrow therapeutic index—such as cyclosporine and tacrolimus—are especially vulnerable to interactions.[62]

Clinical Experience and Pediatric Data.

Itraconazole has roles in the therapy of numerous fungal infections, including sporotrichosis, endemic mycoses such as coccidioidomycosis,[63] histoplasmosis,[64] and others; superficial mycoses; and allergic bronchopulmonary aspergillosis. There are limited data regarding its use to treat invasive aspergillosis, and its variable absorption and lack of an IV formulation limit use for this condition, in favor of newer triazoles such as voriconazole and posaconazole.[65] However, itraconazole has been evaluated for prophylaxis against *Aspergillus* and *Candida* infections in immunocompromised patients and may be preferable to fluconazole for patients at high risk for invasive aspergillosis. A meta-analysis comparing antifungal prophylaxis strategies for patients undergoing chemotherapy or HSCT found no significant difference in overall mortality or incidence of invasive fungal infections when all studies comparing itraconazole and fluconazole were combined, but when trials of the itraconazole oral suspension form (with greater bioavailability) were analyzed separately, there was a significant reduction in invasive fungal infections with itraconazole.[66] Overall, adverse events leading to discontinuation were more common in patients receiving itraconazole.

There are no pivotal studies of itraconazole prophylaxis in children, and the few children enrolled in the larger prophylaxis studies were not analyzed separately. A phase 1 study in 26 HIV-infected children showed that itraconazole solution was well tolerated and efficacious against oropharyngeal candidiasis, including cases caused by fluconazole-resistant isolates.[67] A single-center nonrandomized study showed similar rates of breakthrough fungal infection (4%–6%) and adverse events (8%–14%) comparing children who received itraconazole ($n = 50$), voriconazole ($n = 50$), or posaconazole ($n = 50$) for antifungal prophylaxis after allogeneic HSCT.[68]

Voriconazole

Voriconazole is a second-generation triazole and a synthetic derivative of fluconazole. Voriconazole combines the broad spectrum of antifungal activity of itraconazole with the increased bioavailability of fluconazole. It is fungicidal against *Aspergillus* and fungistatic against *Candida* spp.[39]

Pharmacology and Toxicities.

Voriconazole is available in IV, oral tablet, and oral suspension formulations. In adults, oral bioavailability is >90%; however, oral bioavailability is more modest in children, ranging from 44% to 65%.[69,70] Pharmacokinetic modeling suggests that this difference can be accounted for by intestinal first-pass metabolism occurring in children, but not adults.[71] Voriconazole is distributed extensively to tissues, including the CNS, and has been used successfully to treat CNS fungal infections.[72,73] Voriconazole undergoes extensive hepatic metabolism by the cytochrome P450 system, and dose adjustment is recommended in individuals with hepatic impairment. High interpatient variability has been observed in voriconazole drug concentrations over a range of doses and coincides in part with genetic polymorphisms in the CYP enzymes.[74] As a result of genetic polymorphisms in the gene encoding CYP2C19, some individuals are poor metabolizers and some are extensive metabolizers.[75] About 5% of white people and 15% to 20% of non-Indian Asians have a slow-metabolizer phenotype.

In addition to genetic variation in voriconazole metabolism, there are important age-related differences with implications for pediatric dosing. In contrast to adults and older children in whom voriconazole metabolism is nonlinear (resulting in marked increases in drug exposure related to relatively small changes in dose), young children have linear metabolism and therefore require much larger proportional doses to achieve adequate drug exposure. This linearity was first identified by initial pharmacokinetic analysis of children from 2 to 11 years old in whom a dose of 4 mg/kg twice daily was needed to provide equivalent drug exposure to adults receiving a dose of 3 mg/kg twice daily.[76] A subsequent population pharmacokinetic study predicted that an IV dose of 7 mg/kg twice daily for children younger than 12 years provided exposure similar to that of adults.[69] However, studies using therapeutic drug monitoring to guide voriconazole dosing have shown that even higher doses are required in many cases to achieve goal trough concentrations >1 µg/mL, with a median dose of 16 mg/kg/day required in children 2 to 12 years of age.[70,74,77] Given the substantial interindividual variability in voriconazole pharmacokinetics, therapeutic drug monitoring of voriconazole levels is recommended to gauge adequacy of treatment and to avoid potential toxicities; target trough concentrations between 1 and 5 µg/mL are recommended.[78]

Main side effects of voriconazole include reversible dose-dependent visual disturbances (increased brightness, blurred vision)[79] in as many as one third of treated patients; elevated serum hepatic transaminases with higher doses[80]; and occasional skin reactions, likely due to photosensitization.[37,81] Less common but serious toxicities include neurotoxicity with prominent visual hallucinations,[82] which is associated with serum trough levels above 5.5 µg/L and must be distinguished from the more common visual disturbances, and prolongation of the QT interval with associated cardiac arrhythmias.[83] Similar to the other triazoles, drug interactions can be problematic owing to inhibition of the CYP enzyme system. For instance, concomitant use with sirolimus can increase concentrations of the immunosuppressant 2- to 10-fold.[84] Intravenous voriconazole is solubilized in sulfobutyl ether β-cyclodextrin (SBECD), and because elimination of cyclodextrin is dependent on glomerular filtration, the vehicle can accumulate in patients with severely impaired renal function; clinical significance of accumulation has not been determined fully.

Clinical Experience and Pediatric Data.

In a randomized clinical trial comparing primary therapy for 277 patients with invasive aspergillosis, voriconazole demonstrated superiority to conventional AMB-D, with >50% of those initially treated with voriconazole achieving complete or partial response, compared with 30% of those treated with conventional AMB-D.[85] Improved survival and tolerance of therapy also were observed among those initially treated with voriconazole. Similar positive experience with voriconazole was noted in an open-label multicenter study of 116 patients with invasive aspergillosis treated with voriconazole as either primary (60 patients) or salvage (56 patients) therapy.[86] Additional analyses also have shown the significant benefit of early administration of voriconazole over AMB-D.[87,88] These data have led voriconazole to be guideline-recommended first-line therapy for invasive aspergillosis.[89]

Despite fungistatic activity against *Candida* spp., voriconazole also is effective in the treatment of *Candida* infections. In a multicenter randomized controlled trial evaluating therapy of esophageal candidiasis in 391 immunocompromised patients, voriconazole was successful in 98% and fluconazole in 95%.[90] In another study of 422 patients with invasive candidiasis, approximately 40% of patients were successfully treated with voriconazole. This rate of success was equivalent to that of AMB-D followed by oral fluconazole.[91]

Voriconazole has been evaluated as empiric antifungal therapy for persistent febrile neutropenia. In a randomized controlled trial including 837 patients with fever and neutropenia, the composite outcome of overall success was similar for patients receiving voriconazole (26%) compared with those receiving L-AmB (30%). More breakthrough fungal infections were diagnosed in patients receiving L-AmB (5.0% vs. 1.9%, $P = 0.02$).[92] Studies evaluating voriconazole for prophylaxis against fungal infections in immunocompromised patients have demonstrated similar efficacy to fluconazole (in the context of intensive monitoring and structured empiric therapy),[93] and superiority to itraconazole[94] and low-dose AMB-D (primarily regarding tolerability).[95]

No comparative study has evaluated efficacy of voriconazole compared with other agents for treatment of invasive fungal infections in children. An open-label, compassionate-use evaluation of the drug in 58 children with proven or probable invasive fungal infection refractory to or intolerant of conventional antifungal therapy demonstrated complete or partial response to therapy in 43% of children with aspergillosis, 50% with candidemia, and 63% with scedosporiosis.[96] Other studies have evaluated pharmacokinetics and safety of voriconazole in children, including at higher drug doses currently recommended.[70,97] In a prospective cohort study of children with proven or probable invasive mold infections, 95 of 131 patients received voriconazole either as monotherapy or in combination with other antifungal agents; overall, 60% of patients had a complete or partial response to therapy.[98]

Voriconazole has not been tested formally in neonates. Because of the reports of visual adverse events in adults and children, there is concern about unknown interactions with the developing retina, and there are no planned clinical trials in neonates.

Posaconazole

Pharmacology and Toxicities.

Posaconazole is a second-generation triazole that became available in the US in 2006. It is closely related to itraconazole, is fungicidal in vitro against *Aspergillus,* and has activity against the Mucorales (agents of mucormycosis), which is an advantage over voriconazole.[99] Posaconazole initially was available only as an oral suspension, but delayed-release tablets and an IV formulation now are available. Both oral formulations are approved by the FDA for use in children 13 years and older; the IV formulation is approved for individuals 18 years and older. The pharmacokinetics and appropriate dosing differ for each formulation. Absorption of the oral suspension is variable and is improved greatly when given with a high-fat meal or in multiple divided doses.[100,101] Absorption of the tablet formulation is less variable and is not dependent on food intake; tablet also can be given once daily, with the 300-mg daily adult dose achieving similar drug exposure to the 200 mg oral suspension dose given 3 times daily.[102] Posaconazole has dose-proportional pharmacokinetics up to 800 mg/day and has a large apparent volume of distribution with slow elimination, suggesting extensive distribution into tissues.[101] Posaconazole has lower CNS penetration than voriconazole; however, there are well-documented cases of clinical success for treatment of CNS fungal infection.[103] Posaconazole is metabolized by glucuronidation and primarily eliminated through the fecal route. Mild or moderate chronic renal impairment has no appreciable effect on the pharmacokinetics of oral posaconazole, but avoidance of the IV formulation is recommended in the setting of moderate or severe renal impairment owing to potential accumulation of the vehicle, SBECD.[104]

Posaconazole is an inhibitor of CYP3A4 metabolism and P-glycoprotein transport and is subject to drug interactions with substrates for these pathways, such as calcineurin inhibitors or benzodiazepines. Posaconazole generally is well tolerated; the most commonly observed side effects are gastrointestinal symptoms with the oral suspension.[105] Rare but serious adverse events include hepatotoxicity and QT interval prolongation with associated cardiac arrhythmias.[99] Administration of the IV formulation as a slow infusion through central venous catheter is recommended because of infusion-site reactions noted with repeated administration.

One retrospective study analyzed the pharmacokinetic profile of posaconazole for 12 pediatric patients (<18 years old) with resistant or refractory invasive fungal infections. These patients received a maintenance dose of 800 mg/day of posaconazole oral suspension given in 2 or 3 divided daily doses, compared with adult patients (18–64 years old) who received a maintenance dose of 800 mg/day. The overall success rate and adverse event profile were similar for pediatric and adult patients.[106] These preliminary data suggested that posaconazole pharmacokinetics are similar in adults and the children examined in this study, but a complete pediatric pharmacokinetic study is underway.

Clinical Experience and Pediatric Data.

Posaconazole has been best studied as antifungal prophylaxis, including a large randomized controlled trial in patients with acute myelogenous leukemia or myelodysplastic syndrome, which demonstrated fewer invasive fungal infections (2%) with posaconazole versus either fluconazole or itraconazole (8%). Survival also was significantly longer in patients who received posaconazole.[107] Similarly, in patients with active graft-versus-host disease, posaconazole was similar to fluconazole in preventing any invasive fungal infection, but superior to fluconazole in preventing invasive aspergillosis as well as reducing deaths due to invasive fungal infections.[108]

Posaconazole also has been evaluated for treatment of oropharyngeal and esophageal candidiasis in HIV-infected patients. Posaconazole demonstrated comparable efficacy with fluconazole in the initial treatment of oropharyngeal candidiasis, and significantly lower rates of relapse.[109] Posaconazole also performed favorably in treatment of oropharyngeal or esophageal candidiasis refractory to treatment with fluconazole or itraconazole; a favorable clinical response was observed in 75% to 85% of cases.[110,111]

Although current FDA-approved indications are limited to antifungal prophylaxis and oropharyngeal candidiasis, promising data have emerged for posaconazole in treatment of other invasive fungal infections. Posaconazole showed a survival benefit over historical controls in treating invasive aspergillosis as salvage antifungal therapy,[112] and demonstrated a success rate of 72% in treating invasive aspergillosis that was refractory to voriconazole,[113] but posaconazole has not been examined as primary therapy. Owing to lack of voriconazole activity against the Mucorales group, there is excitement because of posaconazole activity in vitro as well as clinical efficacy as a salvage therapy against these emerging infections.[114] A review of 96 case reports describing posaconazole as combination or second-line therapy for mucormycosis found an approximately 70% rate of complete or partial response, but the true success rate likely is lower because of publication bias.[115] Small, uncontrolled studies also have suggested a role for posaconazole in the treatment of coccidioidomycosis.[116,117]

Experience with posaconazole in children is limited. A retrospective cohort study of 60 children younger than 12 years who received posaconazole prophylaxis after allogeneic HSCT demonstrated no breakthrough invasive fungal infections occurring during the prophylaxis period (up to 200 days after transplantation) and no severe adverse events.[118] The oral suspension was given at doses of either 5 mg/kg/dose twice daily or 4 mg/kg/dose 3 times daily, with higher trough levels noted on the 3-times-daily regimen. An open-label study of 8 patients with chronic granulomatous disease and invasive mold infection treated with posaconazole salvage therapy included 7 pediatric patients. All patients had received itraconazole prophylaxis and had prior antifungal therapy with either voriconazole, caspofungin, or a lipid formulation of amphotericin B.[119] There was complete response with posaconazole in 7 of 8 patients, including 6 of 7 pediatric patients. A subsequent multicenter retrospective survey of 15 children 3 to 17 years of age with invasive fungal infections refractory to first-line therapy demonstrated complete or partial response to posaconazole therapy in 9 patients and no severe adverse events, although mild adverse events were reported in 11 patients.[120] Posaconazole will have an important role in antifungal management in the future, but devoted pediatric clinical studies, to determine both the optimal dosing in children and comparative efficacy, have yet to be performed.

Isavuconazole

Pharmacology and Toxicities.

Isavuconazole, formulated in IV and oral capsule preparations as a prodrug, isavuconazonium sulfate, was approved by the FDA in 2015 for treatment of invasive aspergillosis and mucormycosis in adults. Isavuconazole has a broad spectrum of activity including *Candida, Cryptococcus, Aspergillus,* and the Mucorales, combined with a favorable pharmacokinetic profile.[121] The prodrug, isavuconazonium, is rapidly cleaved by plasma esterases to isavuconazole. Oral bioavailability is 98% with low intersubject variability and no clinically significant food effect.[122,123] It is water soluble with high protein binding and a large volume of distribution, indicating likely high tissue penetration. Animal studies indicate good CNS penetration and likely efficacy in CNS infection.[124] It exhibits dose-proportional pharmacokinetics with moderate deviation from linearity.[122,123] Elimination is primarily through hepatic metabolism; prolonged half-life allows once-daily dosing after initial loading doses.[122,123] Because of high water solubility, the IV formulation of isavuconazole does not require the SBECD carrier that is needed for voriconazole and posaconazole IV formulations; thus it can be used in the setting of significant renal impairment without risk for accumulation.

Isavuconazole is both a substrate and an inhibitor of CYP3A4 and is therefore subject to clinically significant drug-drug interactions with CYP3A4 substrates, inhibitors, or inducers. The most frequently reported adverse events in clinical trials are gastrointestinal symptoms, headache, elevated serum hepatic enzyme concentrations, hypokalemia, dyspnea, cough, peripheral edema, and back pain.[125,126] The overall occurrence rates of adverse events were similar between isavuconazole and voriconazole, but drug-related adverse events were less frequent with isavuconazole, and the frequency of dermatologic and visual adverse events was lower with isavuconazole.[125,126] The frequency and severity of hepatotoxicity also was lower with isavuconazole. Isavuconazole causes dose-related shortening of the QT interval; although the clinical significance of this effect is uncertain, it is contraindicated in individuals with familial short QT syndrome.[126]

Clinical Experience and Pediatric Data.

In a phase 2 randomized controlled trial comparing three isavuconazole oral dosing regimens (including a once-weekly regimen) with oral fluconazole for treatment of esophageal candidiasis in immunocompromised patients, all three regimens were noninferior to fluconazole.[127] Rates of endoscopically confirmed cure were 95% to 98% for the isavuconazole regimens and 95% for fluconazole. Another phase 2 dose-escalation study evaluated IV isavuconazole for antifungal prophylaxis in 20 patients with neutropenia during chemotherapy for acute myeloid leukemia, with a primary end point of safety.[128] Doses of 200 mg and 400 mg once daily were well tolerated with no serious drug-related adverse events; two patients in the low-dose group were diagnosed with possible invasive fungal infections. A phase 3 randomized controlled trial compared isavuconazole with voriconazole for treatment of invasive aspergillosis and other invasive mold infections in 516 immunocompromised adults.[126] On the primary end point of all-cause mortality at 6 weeks, isavuconazole was noninferior to voriconazole, with 18.6% mortality versus 20% mortality for voriconazole. Overall treatment success at the end of treatment was also comparable between groups. An open-label noncomparative trial evaluated isavuconazole for treatment of 37 patients with proven or probable invasive mucormycosis, either as primary or salvage therapy.[126] All-cause mortality at 6 weeks was 38%, and overall response at end of therapy was 31%; in light of the severe natural history of invasive mucormycosis, this trial supports clinical efficacy of isavuconazole in the treatment of mucormycosis. An additional clinical trial is underway evaluating isavuconazole for treatment of invasive candidiasis. There are currently no reported pediatric clinical studies of isavuconazole.

Echinocandins

An entirely new class of antifungal agents compared with long previous development of modified existing classes, the echinocandins, interferes with cell wall biosynthesis by noncompetitive inhibition of 1,3-β-D-glucan synthase, an enzyme present in fungi but absent in mammalian cells.[37] This enzyme produces 1,3-β-D-glucan, which forms a fibril of three helically entwined linear polysaccharides and provides essential structural integrity to the fungal cell wall.[129,130]

Echinocandins are fungicidal against *Candida* but fungistatic against *Aspergillus* because they inhibit hyphal tip and branch point growth, converting the mycelium to small clumps of cells; older septated cells with little glucan synthesis are not killed.[131] Echinocandins are not metabolized through the CYP enzyme system, lessening some of the drug interactions and side effects seen with the azoles. Because of their large molecular weights, the echinocandins have poor oral bioavailability and therefore are only available as parenteral formulations. All three are highly protein bound and have relatively poor distribution to the CNS, ocular fluids, and urine. Because 1,3-β-glucan is a selective target present only in fungal cell walls and not in mammalian cells, the echinocandins have few adverse effects.[129] Important pharmacologic distinctions are reviewed briefly for each agent.

Caspofungin

Pharmacology and Toxicities.

Caspofungin is a semisynthetic derivative of the natural product pneumocandin B_0. Caspofungin has triphasic pharmacokinetics, with modest nonlinearity.[132] Tissue distribution accounts for an initial rapid decline in plasma levels, and subsequently the drug undergoes slow hepatic metabolism through hydrolysis and *N*-acetylation.[132,133] The drug also undergoes spontaneous degradation; these processes together account for a terminal half-life of 27 to 50 hours. Inactive metabolites are excreted in the feces and urine. A loading dose is required to achieve steady-state levels quickly.

At present there is no known maximal tolerated dose and no toxicity-defined maximal length of therapy. Elevations of caspofungin plasma concentrations are observed in patients with mild hepatic insufficiency and a dose reduction in adults from 50 mg to 35 mg daily following the standard 70 mg loading dose is recommended in this setting. Plasma concentrations of tacrolimus are reduced by about 20% when coadministered with caspofungin, but tacrolimus does not alter the pharmacokinetics of caspofungin.[133] Cyclosporine increases the concentration of caspofungin by about 35%, but plasma concentrations of cyclosporine are not altered by coadministration of caspofungin.[133] Rifampin, efavirenz, nevirapine, phenytoin, dexamethasone, and carbamazepine increase the clearance of caspofungin; if caspofungin is coadministered with these drugs, an increased maintenance dose should be considered.[133]

A pharmacokinetic study conducted in 39 children 2 to 17 years of age evaluated caspofungin dosing based on both weight (1 mg/kg/day) and body surface area (50 or 70 mg/m^2/day).[134] Compared with plasma concentrations attained in adults treated with 50 mg/day, the weight-based approach resulted in suboptimal plasma concentrations, whereas the 50 mg/m^2/day dose yielded similar plasma concentrations in children. Caspofungin half-life is approximately one third shorter in children than in adults. Based on this initial study, dosing in children begins with a loading dose of 70 mg/m^2 followed by daily maintenance dosing of 50 mg/m^2. Pharmacokinetic data are limited in neonates, but a dose of 25 mg/m^2 daily in this age group appears to provide drug exposure comparable with an adult dose of 50 mg/day.[135]

A retrospective analysis of compassionate-use caspofungin in 25 immunocompromised children, most of whom also received other antifungal agents, noted that only 3 (12%) had a possible drug-related adverse event, which included hypokalemia and elevated serum bilirubin or hepatic transaminase concentrations.[136] Another study of 64 immunocompromised children revealed that caspofungin was not discontinued in any patients because of adverse events, and clinical adverse events were mild to moderate and observed in 34 patients (53%).[137] Mean serum aspartate aminotransferase and alanine aminotransferase values were slightly higher at end of therapy, but creatinine, bilirubin, and alkaline phosphatase levels were not different from baseline.

Clinical Experience and Pediatric Data.

In a noncomparative clinical trial of 83 adults with invasive aspergillosis who were intolerant of or had infections refractory to conventional antifungal therapy, caspofungin demonstrated potential utility as salvage therapy.[138] Approximately 45% of patients (37/83) had a complete or partial response, including 50% (32/64) with pulmonary aspergillosis and 23% (3/13) with disseminated aspergillosis. Subsequent noncomparative studies evaluating caspofungin as primary therapy for invasive aspergillosis showed complete or partial responses to therapy in 33% of adults with hematologic malignancies or undergoing autologous HSCT,[139] and 42% in adult allogeneic HSCT recipients.[140]

A randomized controlled trial comparing caspofungin with conventional AMB-D in 224 adults with invasive candidiasis found that caspofungin was at least equivalent, with response rates of 81% and 65%, respectively.[141] Caspofungin was at least comparable with AMB-D against all the major species of *Candida*. Mortality was similar in both groups. However, drug-related adverse events were more common in the AMB-D group.[141] Randomized controlled trials comparing caspofungin with L-AmB for empiric therapy of persistent febrile neutropenia have shown that caspofungin was comparable with L-AmB in efficacy in both adults[142] and children.[143]

A multicenter retrospective survey in Germany analyzed 64 immunocompromised children who received caspofungin for refractory infection ($n = 38$), intolerance of standard agents ($n = 10$), or as the best perceived therapeutic option ($n = 16$).[137] Overall survival was 75% at end of therapy, and complete or partial response to therapy was observed in 70% of patients with proven infections and 50% of those with probable infections. A multicenter, open-label comparative study evaluating the safety, tolerability, and efficacy of caspofungin in 49 children with documented

Candida or *Aspergillus* infections found similarly high rates of success as in adults, with success at end of therapy observed in 50% of patients with invasive aspergillosis and 81% of patients with invasive candidiasis.[144] Caspofungin appears to be well tolerated in children.

There are limited reports of caspofungin use in neonates, mainly for salvage therapy in cases of refractory invasive candidiasis.[145]

Micafungin

Pharmacology and Toxicities.

Micafungin is an echinocandin lipopeptide compound with a half-life of approximately 12 hours.[37,146,147] In contrast to caspofungin, micafungin has simple linear elimination kinetics. It undergoes limited hepatic metabolism by arylsulfatase, catechol *O*-methyltransferase, and hydroxylation, with predominantly biliary excretion. Drug-drug interactions are uncommon.

Dosage of micafungin varies with age because of differences in clearance. Particularly in neonates, in whom high drug levels in the CNS are desired, a higher dose is needed to achieve adequate exposure. A study of safety and pharmacokinetics of micafungin in young infants with suspected *Candida* infection found that micafungin doses of 7 and 10 mg/kg/day were well tolerated and provided exposure shown in animal models to be adequate for treatment of CNS infection.[148] In preterm infants, a dose of 15 mg/kg was shown to approximate drug exposure of a 5-mg/kg adult dose.[149] A population pharmacokinetic study based on these clinical studies showed that desired target attainment was likely at a dose of 10 mg/kg/day for most neonates and young infants.[150]

Micafungin doses up to 4.5 mg/kg/day have been shown to be well tolerated in children and adolescents with pharmacokinetics more similar to adults.[151,152] A population pharmacokinetic study of micafungin in children and adolescents found that a dose of 2 mg/kg/day was appropriate for most children to achieve target exposure for treatment of invasive candidiasis.[153]

Clinical Experience and Pediatric Data.

A randomized controlled trial comparing micafungin to L-AmB for treatment of invasive candidiasis in 531 patients found that micafungin was as effective as L-AmB with 89% success rates in each group.[154] There was a lower incidence of adverse events leading to drug discontinuation in the micafungin group. This trial also included children, and a separate analysis of the 106 pediatric patients showed similar findings to the parent study.[155] Micafungin also demonstrated noninferiority to caspofungin for treatment of invasive candidiasis in adults.[156] Other studies have demonstrated the efficacy of micafungin in the primary therapy of esophageal candidiasis[157]

Micafungin was studied in a noncomparative manner in adults and children with invasive aspergillosis, either micafungin alone or in combination with other antifungal agents.[158] A favorable response to therapy was seen in 80 (35%) of 225 of patients; relatively few patients received micafungin monotherapy. In the subset of patients who had undergone hematopoietic stem cell transplantation, the overall complete or partial response rate was 26%.[159]

Micafungin also has been evaluated for use as antifungal prophylaxis. A study conducted in 882 adult and pediatric HSCT recipients found that micafungin was more effective than fluconazole in preventing invasive fungal infections, with 80% remaining infection free in the micafungin arm compared with 74% in the fluconazole arm.[160] This study included 84 patients younger than 16 years and found that the success in those patients was 69% (27/39) in the micafungin arm and 53% (24/45) in the fluconazole arm. Another study comparing micafungin with itraconazole for prophylaxis against invasive fungal infections in HSCT recipients found that micafungin was comparable in efficacy but was better tolerated, with lower rates of drug-related adverse events and greater likelihood of study completion.[161] At present there are no large-scale clinical trial reports of micafungin in neonates.

Anidulafungin

Pharmacology and Toxicities.

Anidulafungin is the most recently developed echinocandin and currently is not licensed for use in children. It does not undergo metabolism but is eliminated through spontaneous degradation with linear kinetics and a terminal half-life of 40 to 50 hours.[162]

Activity in vitro is similar to that of the other echinocandins.[163] Neither end-stage renal impairment nor dialysis substantially alters the pharmacokinetics of anidulafungin.[164] Dose adjustment is not needed for hepatic insufficiency.[162] Tissue concentrations after multiple dosing were highest in lung and liver, followed by spleen and kidney, with measurable concentrations in the brain tissue similar to the other echinocandins. There are no known clinically significant drug-drug interactions. Infusion-related adverse events such as flushing, urticaria, and hypotension have been observed but are reduced by slowing the infusion to less than 1.1 mg/min.[162] Otherwise, anidulafungin is well tolerated.

The pharmacokinetics of anidulafungin in children are similar to those in adults; children receiving a maintenance dose of 0.75 mg/kg/day have similar drug exposure to adults receiving a dose of 50 mg/day (recommended for esophageal candidiasis), and children receiving 1.5 mg/kg/day have similar exposure to adults receiving a dose of 100 mg/day (recommended for invasive mycoses).[165] In neonates and young infants, a maintenance dose of 1.5 mg/kg/day achieved similar exposure to the same weight-based dose in children and to an adult dose of 100 mg/day. Anidulafungin was well-tolerated by both infants and children with no serious drug-related adverse events reported in either pharmacokinetic study.[165,166]

Clinical Experience and Pediatric Data.

A study of 601 patients with esophageal candidiasis compared anidulafungin with oral fluconazole and found successful outcomes of >95% as assessed by endoscopy.[167] A subsequent study found superiority of anidulafungin over fluconazole for treatment of invasive candidiasis, with successful treatment response at end of therapy of 75% versus 60%, respectively, solidifying the role of the echinocandins in treating invasive candidiasis.[168] A multicenter randomized controlled trial is underway comparing anidulafungin with fluconazole for treatment of invasive candidiasis in children.

Topical Antimicrobial Agents

Ishminder Kaur, Jane M. Gould

Topical antimicrobial therapy dates back to ancient times, when a wide variety of substances such as grease, lint oil, wine, and metallic salts were applied to wounds. Since then, topical antibiotics have been developed. They are most frequently used to treat infections affecting the skin and mucous membranes. Agents include topical preparations of parenterally administered antibiotics, as well as antibiotics and antiseptics not given by any other route because of their toxicity. As a general principle, agents used topically should not be those relied on for systemic use because resistance develops rapidly. Precise recommendations for use of topical agents are limited by the difficulty of in vitro assays, establishment of breakpoints for susceptibility, effect of the vehicle on delivery, and lack of clinical efficacy trials. Antifungal and antiviral agents are described in Chapters 293 and 295.

Ophthalmic Therapy

Antibiotics administered topically are used for the prophylaxis and treatment of many ophthalmologic pathogens. Topical agents are used for the prophylaxis of neonatal conjunctivitis, perioperative infections, and ophthalmologic trauma such as corneal abrasions, foreign bodies, and ruptured globes. They are used for the treatment of blepharitis, chronic dacryocystitis, conjunctivitis, corneal ulcers, and endophthalmitis. Selection of an antimicrobial agent should be based on its activity against the most likely pathogenic organisms and lack of adverse effects. Ophthalmic topical antimicrobial agents, their spectrum of activity, and adverse events are shown in Table 294.1.[1–13] Different routes of administration (topical, subconjunctival, retrobulbar, and intravitreal) can be used, depending on the site of infection. Formulations are available as suspensions, ointments, solutions, and extemporaneously prepared "fortified drops" (Table 294.2). To optimize antibiotic delivery, devices impregnated with antibiotics, such as collagen shields that prolong antibiotic contact with ocular surface, have been used for corneal protection after trauma, but lack of clinical trials limit their use in ocular infections.[14,15]

TABLE 294.1

Commercially Available Topical Ophthalmic Antimicrobial Agents

			Spectrum of Activity	
	Concentration	**Mechanism of Action**	**Gram-Positive Organisms**	**Gram-Negative Organisms**[a]
SINGLE AGENTS				
Azithromycin (Azasite)	Solution, 1%	Inhibits protein synthesis	+++	++
Bacitracin (generic)	Ointment, 500 U/g	Inhibits early steps in peptidoglycan biosynthesis, thus inhibiting cell wall synthesis; also changes membrane permeability	+++ (group B *Streptococcus,* usually R)	+ (Enterobacteriaceae and *Pseudomonas* spp. R)
Besifloxacin (Besivance)	Solution, 0.6%	Inhibits DNA gyrase and topoisomerase IV	+++	+++
Chloramphenicol (generic)	Ointment, 1% Solution, 0.5%	Inhibits protein synthesis	++ (*Staphylococcus aureus* R)	+++ (*Pseudomonas* spp. R)
Ciprofloxacin (Ciloxan)	Ointment, solution, 0.3%	Inhibits DNA gyrase	++	+++

Erythromycin (generic)	Ointment, 0.5%	Inhibits protein synthesis	+++	+/− (Enterobacteriaceae and *Pseudomonas* spp. R)
Gatifloxacin (Zymar)	Solution, 0.3%	Inhibits DNA gyrase and topoisomerase IV	+++	++
Gentamicin (generic)	Ointment, 0.3% solution, 0.3%	Inhibits protein synthesis	−	+++
Levofloxacin (Quixen)	Solution, 0.5%	Inhibits DNA gyrase and topoisomerase IV	+++	++
Moxifloxacin (Vigamox)	Solution, 0.5%	Inhibits DNA gyrase and topoisomerase IV	+++	++
Norfloxacin (Chibroxin)	Solution, 0.3%	Inhibits DNA gyrase	++	+++
Ofloxacin (Ocuflox)	Solution, 0.3%	Inhibits DNA gyrase	++	++
Povidone-iodine	Solution, 2.5%	Unknown	+++	+++
Silver nitrate	Solution, 1%	Inhibits DNA replication; modifies cell membrane and disrupts superficial cells[11]	+	++
Sulfacetamide (generic)	Ointment, 10% Solution, 10%, 15%, 30%	Inhibits folic acid synthesis	++	++ (*Pseudomonas* spp. R)
Sulfisoxazole diolamine (Gantrisin)	Ointment, 4% Solution, 4%	Inhibits folic acid synthesis	++	++ (*Pseudomonas* spp. R)
Tetracycline (Achromycin)	Solution, 1%	Inhibits protein synthesis	+	++ (*Pseudomonas* spp. R)
Tobramycin (generic)	Ointment, 0.3% solution, 0.3%	Inhibits protein	−	+++
COMBINATION PREPARATIONS				
Neomycin + Polymyxin	Various concentrations	Inhibits protein synthesis	+	++ (*Pseudomonas* spp.

B/bacitracin + Polymyxin B + Polymyxin B/gramicidin				R)	
Polymyxin B + Bacitracin + Neomycin + Neomycin/bacitracin + Neomycin/gramicidin + Oxytetracycline + Trimethoprim	Various concentrations	Attaches to cell membrane, with disruption of osmotic properties leading to cell death	−	+++ (*Neisseria gonorrhoeae* R, *Proteus* spp. R)	
Trimethoprim + Polymyxin B	Various concentrations	Inhibits dihydrofolic acid reductase	++	++ (*Pseudomonas* spp. and *Neisseria gonorrhoeae* R)	
Gramicidin + Polymyxin B/neomycin	Various concentrations	Uncouples oxidative phosphorylation	++	−	

[a]Gram-negative organisms include *Haemophilus* spp., *Neisseria* spp., Enterobacteriaceae, and *Pseudomonas* spp., unless otherwise indicated.

+++, excellent activity and spectrum; ++, good activity and spectrum; +, fair activity and spectrum; −, no activity; ND, no or limited data; R, resistant.

TABLE 294.2

Commonly Used Fortified Ophthalmic Drops

Antibiotic	Concentration
Amikacin	6.7 mg/mL
Bacitracin	9600 U/mL
Carbenicillin	6.2 mg/mL
Cefazolin	33 mg/mL
Gentamicin	14 mg/mL
Neomycin	33 mg/mL
Oxacillin	66 mg/mL
Penicillin G	333,000 U/mL
Pipercillin	12.5 mg/mL
Ticarcillin	6.3 mg/mL
Tobramycin	5 mg/mL
Vancomycin	31 mg/mL

Adapted from Baum JL. Antibiotic use in ophthalmology. In: Tasman W, Jaeger EA (eds). Duane's Clinical Ophthalmology. Philadelphia, Lippincott-Raven, 1989, pp. 1–20.

Blepharitis

Blepharitis is commonly caused by *Staphylococcus aureus,* and treatment consists of the topical application of an antistaphylococcal agent in ointment form to the eyelids.

Dacryocystitis

Acute dacryocystitis and dacryoadenitis are commonly caused by *S. aureus* and should be treated systemically. Chronic dacryocystitis is not usually infectious, but infection can occur secondary to stasis and obstruction of the lacrimal duct. Treatment consists of relief of the obstruction by irrigation of the lacrimal outflow tract. The use of a topical antibiotic is controversial.[6]

Conjunctivitis

Acute conjunctivitis in children is bacterial in >50% of cases[16]; nontypable *Haemophilus influenzae*, *Streptococcus pneumoniae,* and *Moraxella catarrhalis* are the most common causative agents. Although conjunctivitis usually is self-limited, treatment with topical antibiotics has been shown to hasten the rate of clinical and microbiologic resolution.[17–19] Treatment consists of a topical agent in solution form (sulfacetamide, erythromycin, azithromycin, gentamicin, gatifloxacin, ofloxacin, or besifloxacin) that has activity against major pathogens. Topical preparations of aminoglycosides and fluoroquinolones have been shown to be equally efficacious (84%–90%) in the treatment of acute conjunctivitis,[20] but these topical preparations should be reserved for serious infections when gram-negative bacilli are causative, especially *Pseudomonas aeruginosa.* Further, topical fluoroquinolones (moxifloxacin) were not shown to be superior compared with polymyxin B −trimethoprim in a randomized controlled trial for treatment of acute conjunctivitis in children.[17c] It is important to keep in mind that drops are washed out rapidly in a crying child. In infants, ointments may be preferable for ease of application, but the resultant visual blurring can be discomforting to older children. When otitis media accompanies conjunctivitis, as is frequently the case with nontypable *H. influenzae,* treatment should consist of the administration of an appropriate antibiotic orally; concomitant topical therapy is not necessary. Such is also the case for chlamydial conjunctivitis, which is treated systemically to eradicate nasopharyngeal colonization; topical therapy is not necessary.

Neonatal Conjunctivitis

Antibiotic prophylaxis has greatly reduced the incidence of ophthalmia neonatorum in the United States. The use of topical silver nitrate reduced the incidence of gonococcal ophthalmia neonatorum from 10% to 0.3%.[21] Silver nitrate is no longer available in the United States, causes chemical conjunctivitis in 10% of patients,[22] and has been replaced by ocular prophylaxis using 0.5% erythromycin ointment.[22–24] Neither agent is effective prophylaxis against chlamydial infection. A 2.5% povidone-iodine solution was shown to be effective in preventing ophthalmia neonatorum in a study in Kenya, demonstrating efficacy against *Neisseria gonorrhoeae* similar to that of erythromycin or silver nitrate and superiority against *Chlamydia trachomatis*.[12] In another comparison study conducted in Israel, 1% tetracycline was found to be marginally more effective than 2.5% povidone iodine[25]; however, testing for *C. trachomatis* was limited to serology. In 2015, the Canadian Pediatric Society advocated against universal topical prophylaxis, favoring screening of mothers for *C. trachomatis* and *N. gonorrhoeae*.[26]

Keratitis

Bacterial infections causing corneal ulceration are rare in children and most commonly follow corneal abrasion, a scratch, or a foreign-body injury. Usual bacterial etiologies include *S. aureus,* coagulase-negative staphylococci (CoNS), *S. pneumoniae, M. catarrhalis,* and gram-negative bacilli, especially *P. aeruginosa.*[27] Adequate evaluation and treatment are essential to prevent permanent corneal injury. For existing infection, Gram stain and culture of the ulcer surface are essential to determine the causative organism, direct antimicrobial therapy, and distinguish bacterial keratitis from herpetic and fungal keratitis. Treatment consists of frequent topical administration of antimicrobial agents.

The achievable concentration of antibiotic in corneal stroma after topical application is limited because the corneal epithelium is a barrier to drug transport. The damaged cornea allows greater penetration of antibiotics into the cornea, and lipophilic antibiotics such as chloramphenicol achieve higher concentrations. "Fortified drops" are solutions prepared extemporaneously to contain higher concentrations of antibiotics than available commercially, or antibiotics not commercially available for ophthalmic application; they are used frequently for the treatment of bacterial corneal ulcers and endophthalmitis[6,13] (see Table 294.2). Monotherapy with moxifloxacin 0.5% was shown in a randomized trial to be equally effective compared with combination of fortified antibiotics (cefazolin and tobramycin for treatment of nonperforated bacterial corneal ulcers).[28]

The average drop volume far exceeds the capacity of the inferior cul-de-sac of the eye; spillage or drainage into the lacrimal sac is rapid.[6] Drug draining through the lacrimal system is absorbed systemically and may be of sufficient amount in patients with hepatic or renal insufficiency to cause toxicity. To avoid lacrimal sac drainage and systemic absorption, the puncta in the medial canthal area can be occluded by digital pressure for 15 to 20 seconds after administration of an eyedrop.[4] Systemic antibiotics have little role in the treatment of bacterial corneal ulcers because concentrations achieved in the cornea are inferior to those attained by topical or subconjunctival administration.

Endophthalmitis

Infectious endophthalmitis is a virulent, sight-threatening infection of intraocular tissue. Prompt diagnosis and therapy are essential. Risk factors for endophthalmitis include ocular trauma or surgery, periocular infection, and systemic infection. Common bacterial pathogens include *S. aureus*, CoNS, streptococci, and gram-negative bacilli, especially Enterobacteriaceae and *P. aeruginosa*.[29] When endophthalmitis is suspected, aspiration of vitreous humor for culture is essential to determine the pathogen or pathogens and to guide antimicrobial therapy. The corneal epithelium, retinal capillaries, and pigmented retinal epithelium provide mechanical barriers to antimicrobial penetration into the vitreous humor. In addition, the flow of aqueous humor anteriorly impairs the movement of drugs to the vitreous humor. Thus administration of antibiotics by the topical, subconjunctival, or systemic route may not achieve an adequate intravitreal concentration (Table 294.3). The optimal route of administration is intravitreal instillation (see Chapter 84). Many parenterally administered antibiotics have been used for intravitreal injection (Table 294.4). Current recommendation for empiric therapy include intravitreal instillation of vancomycin plus ceftazidime.[30] Disadvantages of intravitreal administration are possible damage to the retina and intraocular structures, as well the need for anesthesia for injection. Adjuvant therapy consists of subconjunctivally and parenterally administered antibiotics, vitrectomy, and corticosteroids (systemically, intraocularly, or by both routes).[13]

TABLE 294.3

Concentrations of Antimicrobial Agents Within Human Eyes After Systemic Administration

Antibiotic	Dosage	Vitreous Humor (Uninflamed Eye) (μg/mL)
Cefazolin	2 g IV	0.3–4.6
Cefotaxime	1 g IM	<0.2
Chloramphenicol	3 g PO	5–15
Ciprofloxacin[102]	1000 mg PO	0.3–1.2
Gentamicin	1.6 mg/kg IM	<0.2
Imipenem	1 g IV	1.4–3.6[a]
Levofloxacin	600 mg PO[103]	1.5 ± 0.5
	500 mg PO[104]	0–1.6
Linezolid[105]	600 mg IV	1.8–2.4
	600 mg PO × 2 (every 12 hr)	3.6–5.2
Ofloxacin[106]	400 mg PO	1.8 ± 0.2
Oxacillin	2 g IV	<0.2–4.5

[a] A concentration of 13 μg/mL was achieved in one patient with an inflamed eye.

IM, intramuscular; IV, intravenous; PO, oral.

Partially Adapted from Barza M. Antibacterial agents in treatment of ocular infections. Infect Dis Clin North Am 1989;3:533.

TABLE 294.4

Typical Dosage of Antibiotics for Subconjunctival and Intravitreal Administration[a]

Antibiotic	Dose		
	Subconjunctival (mg)	Intravitreal (μg)[b]	Interval (hr)
Amikacin[c]	40	400	24–48
Amphotericin	NR	5–10	NR
Ampicillin	100	5000	48

Cefazolin	100	2250	24
Ceftazidime	100	2250	48–72
Ceftriaxone	125[107]	NR	NR
Cefuroxime	NR	1000	48–72
Ciprofloxacin	NR	100	12
Clindamycin	30	1000	72
Fluconazole	1 mL of 0.2% solution	NR	NR
Gentamicin	20[d]	200	72–96
Methicillin	100	2000	NR
Penicillin G	NR	2–4000U	48
Tobramycin	20	200–400	NR
Vancomycin[e]	25	1000	72
Voriconazole	NR	50–200	NR

[a] Partially adapted from Radhika M, Mithal K, Bawdekar A, et al. Pharmacokinetics of intravitreal antibiotics in endophthalmitis. J Ophthalmic Inflamm Infect 2014;4:22; and Lemley CA, Han DP. Endophthalmitis: a review of current evaluation and management. Retina. 2007;27:662–680. Intervals are those reported in studies referenced. Doses are based primarily from studies in adults.

[b] Each drug is diluted to provide the indicated dose (μg) in a volume of 0.1 mL (sterile water or normal saline. 1 μg = 0.001 mg.

[c] Less toxic to the retina than gentamicin or tobramycin when given intravitreally.

[d] In children who weight <40 kg, the dose should not exceed half of a single intravenous dose.

[e] May cause tissue necrosis/sloughing when administered subconjunctivally.

NR, not reported in studies referenced.

For treatment of endogenous fungal endophthalmitis, systemically administered antifungal agents have variable penetration into the posterior segment of the eye. Therapeutic concentrations of fluconazole and voriconazole usually can be achieved, but not amphotericin B, posaconazole, or the echinocandins.[31] Intravitreal injection of amphotericin B (5–10 μg) or voriconazole (100 μg) usually is used for sight-threatening involvement to achieve high local antifungal activity as rapidly as possible.

Otic Therapy

Topical antibiotic therapy is used in the treatment of otitis externa and chronic suppurative otitis media (CSOM) and as prophylaxis for surgery. Controlled studies documenting efficacy or assessing safety are generally lacking.

Otitis Externa

Otitis externa describes an inflammatory condition of the auricle, ear canal, or outer surface of the tympanic membrane. Infectious etiologies include primarily bacteria (most commonly *S. aureus, P. aeruginosa,* and anaerobic bacteria), followed by fungi and mycobacteria.[32,33] Therapy for otitis externa consists of cleansing of the canal, elimination of pathogens, reduction of the accompanying inflammation and edema, symptomatic relief, restoration of the oil and water content of the skin, and elimination or control of predisposing factors. Topical antimicrobial agents are noninferior to systemic antibiotics and are effective as sole agents for uncomplicated acute otitis externa.[34,35] The spectrum of activity and adverse events of the most commonly used topical antibiotics are shown in Table 294.5.[7,10,36–38] Commercial preparations for the treatment of external otitis are combinations of broad-spectrum antibiotics, often with anti-inflammatory agents (Table 294.6). Topical ciprofloxacin (with hydrocortisone), ofloxacin, and finafloxacin have been shown to be effective treatment of otitis externa and are approved by the United States Food and Drug Administration (FDA) for patients older than 1 year.[39–43] Topical antibacterial therapy for otitis externa should be used in conjunction with aural toilet to hasten cure and because prolonged use of topical agents alone can induce fungal overgrowth.

TABLE 294.5

Topical Otic Antimicrobial Agents

Agent	Concentration	Mechanism	Spectrum of Activity		Adverse Effects
			Gram-Positive Organisms	Gram-Negative Organisms[a]	
Acetic acid	36% solution	Unknown	ND	*Pseudomonas aeruginosa*[36,37]	
Boric acid	2.75%–5% solution	Unknown	ND; yeasts > bacteria[38]	ND	Marked system absorption can lead to shock ar death
Ciprofloxacin (Cipro HC Otic)	Ciprofloxacin, 2 mg/mL Hydrocortisone, 10 mg/mL	Interferes with DNA gyrase	++	+++ *Pseudomonas aeruginosa*	Pruritus rarely
Colistin (polymyxin	3 mg/mL	Same as polymyxin	–	++ (*Pseudomonas*	Renal toxicity; neurotoxicity if

E)				spp. R)	absorbed
Modified Burow solution (water, aluminum, and sodium acetate)		Unknown	ND	ND	
Finafloxacin (Xtoro)	0.3% suspension	Inhibits DNA gyrase and DNA topoisomerase IV	+ *Staphylococcus aureus*	+ *P. aeruginosa*	Nausea and pruritus in 1% studied patients
Neomycin	3.3–3.5 mg/mL	Inhibits protein synthesis	+	++ (*Pseudomonas* spp. R)	Contact hypersensitivity
Ofloxacin (Floxin)	0.3% solution	Interferes with DNA gyrase	++	+++	Taste perversio pruritus, site irritation; dizziness, earache, and vertigo in ~1% patients studie
Polymyxin B	10,000 U/mL	Attaches to cell membrane, with disruption of osmotic properties leading to cell death	−	+++	Renal toxicity if absorbed

[a] Gram-negative organisms include Haemophilus spp., Neisseria spp., Enterobacteriaceae, and Pseudomonas spp., or as otherwise indicated.

+++, excellent activity and spectrum; ++, good activity and spectrum; +, fair activity and spectrum; −, no activity; ND, no or limited data; R, resistant.

Data from references 7, 10, 33–35,43.

TABLE 294.6

Commercially Available Topical Otic Preparations

Trade Name	Composition
Cipro HC Otic	Ciprofloxacin, 2 mg/mL Hydrocortisone, 10 mg/mL
Ciprodex	Ciprofloxacin, 3 mg/mL Dexamethasone, 1 mg/mL
Coly-Mycin S Otic	Colistin sulfate, 3 mg/mL Neomycin sulfate, 3.3 mg/mL Thonzonium bromide, 0.5 mg/mL Hydrocortisone acetate, 10 mg/mL
Cortisporin (solution, suspension)	Neomycin, 3.5 mg/mL Polymyxin B, 10,000 U/mL

	Hydrocortisone, 10 mg/mL
Floxin	Ofloxacin, 0.3%
LazerSporin-C solution	Neomycin sulfate, 3.5 mg/mL Polymyxin B, 10,000 U/mL Hydrocortisone, 10 mg/mL
Otic Domeboro solution	Acetic acid, 2% Modified Burow solution (water, aluminum acetate, and sodium acetate)
Otic Tridesilon solution	Acetic acid, 2% Desonide, 0.5% (nonfluorinated corticosteroid)
Pedotic suspension	Neomycin sulfate, 3.5 mg/mL Polymyxin B sulfate, 10,000 U/mL Hydrocortisone, 10 mg/mL
Star-Otic ear solution	Acetic acid, 2% Burow solution (aluminum acetate) Boric acid
Tobra Dex	Tobramycin, 0.3% Dexamethasone, 0.1%
VōSol HC Otic	Acetic acid, 2% Hydrocortisone, 10 mg/mL
VōSol Otic	Acetic acid, 2%
Xtoro	Finafloxacin, 0.3%

Chronic Suppurative Otitis Media

CSOM is defined as otorrhea through a nonintact tympanic membrane that lasts >6 weeks and is unresponsive to medical management. This condition usually is a complication of acute otitis media with chronic mastoiditis. The pathogens, however, are different in this condition, with *P. aeruginosa*, *S. aureus*, and anaerobic bacteria most commonly implicated. Therapy usually is systemic antimicrobial therapy in conjunction with aural toilet. A Cochrane Review of 9 trials of patients with CSOM concluded that a topical fluoroquinolone compared with systemic antibiotics was associated with shorter duration of otorrhea.[44]

A study in 44 children with tympanostomy tubes who received topical otic therapy for CSOM did not demonstrate excessive hearing loss, as measured by a change in bone conduction thresholds.[45] Despite the lack of extensive safety data, topical otic agents (see Table 294.5) have been used extensively, alone or in combination with systemic therapy, with apparent success and without adverse effects attributed solely to their use. Cortisporin is used most commonly. Topical ofloxacin is approved by the FDA for the treatment of CSOM in individuals 12 years and older and for acute otitis media in children 1 year and older with tympanostomy tubes because of its microbiologic profile and favorable performance in clinical trials.[46,47] Availability of effective, approved otic antibiotics has supplanted off-label use of ophthalmic aminoglycoside otically. Combined medical therapy and surgical debridement frequently are necessary. Failure of management or the presence of cholesteatoma is an indication for surgical intervention.

Prophylaxis After Tympanostomy Tube Placement

Topical otic therapy has been used as prophylaxis for otorrhea after tympanostomy tube placement. Studies performed to determine whether this strategy is efficacious have had conflicting results. A Cochrane Review of 15 randomized controlled trials concluded that various interventions, including multiple saline washouts, single application of topical antibiotics, and prolonged application of topical antibiotics were effective in reducing otorrhea after tympanostomy tube placement.[48]

Acute Tympanostomy Tube Otorrhea

Acute otorrhea that occurs while the tympanostomy tube is in place is considered to be an episode of acute otitis media. In a recent randomized controlled trial in children with tympanostomy tubes and acute otorrhea, therapy with antibiotic-glucocorticoid drops was shown to be more effective than compared with oral antibiotic therapy or initial observation alone.[49]

Therapy for Skin Infections

Topical antibiotics are used for the prophylaxis and treatment of a wide variety of skin infections (Table 294.7).[50–57] The most common conditions for which the use of topical therapy has been found to be efficacious are acne, impetigo, and burns. Topical antimicrobial agents also often are used at intravascular catheter sites to prevent infection.

TABLE 294.7

Topical Antibiotics for Use on Skin

Agent (Trade Name)	Mechanism of Action	Spectrum of Activity			
		Gram-Positive Organisms	Gram-Negative Organisms[a]	Anaerobes	Yeast
Bacitracin[b] 400, 500 U/g (generic)	Inhibits early steps in peptidoglycan biosynthesis, inhibits cell wall synthesis; changes membrane permeability	+++ (group B *Streptococcus* R)	+ (Enterobacteriaceae R, *Pseudomonas* spp. R)	++	–
Clindamycin, 10 mg/mL (Cleocin)	Inhibits protein synthesis	+++	–	+++	–
Erythromycin, 2%, 3% (many preparations)	Inhibits protein synthesis	+++	++	–	–
Fusidic acid, 2% (Fucidin)	Inhibits protein synthesis	+++	+ (Enterobacteriaceae R, *Pseudomonas* spp. R)	++	–
Gentamicin, 0.1%	Inhibits protein synthesis	+	+++	–	–
Meclocycline, 1% (Meclan)	Inhibits protein synthesis	+	++ (*Pseudomonas* spp. R)		+
Metronidazole, 0.75% (MetroGel)	Interacts with bacterial DNA; precise mechanism unknown	–	–	+++ (*Propionibacterium acnes* R)	–
Mupirocin, 2% (Bactroban)	Inhibits protein synthesis by acting on bacterial isoleucyl transfer RNA synthetase	+++	+/–	–	–
Neomycin, 3.5 mg/g[b] (many)	Inhibits protein synthesis	+	++ (*Pseudomonas* spp. R)	–	–
Polymyxin B[b]	Attaches to cell membrane, with disruption of osmotic properties	–	+++ (*Proteus* spp. R, *Serratia* spp. R)	+ (*Bacteroides fragilis* R)	+/– (in hig concen

	leading to cell death				
Retapamulin 1% ointment (Altabax, Altargo)	Inhibits protein synthesis (novel site of action on SOS ribosomal subunit)	+++	−	+	−
Sulfacetamide, 10% (Novacet, Sulfacet-R)	Inhibits folic acid synthesis	++	++ (*Pseudomonas* spp. R)	−	−
Tetracycline, 2.2 mg/mL (Topicycline)	Inhibits protein synthesis	+	++ (*Pseudomonas* spp. R)	+	−

[a] Gram-negative organisms include *Haemophilus* spp., *Neisseria* spp., Enterobacteriaceae, and *Pseudomonas* spp., unless otherwise specified.

[b] Many commercial preparations combine bacitracin, neomycin, and polymyxin B.

+++, excellent activity and spectrum; ++, good activity and spectrum; +, fair activity and spectrum; −, no activity; R, resistant.

Data from references 8, 10, 50–57.

Acne

Minor acne can be treated with topical antibiotics, keratolytics, and drying agents. Antibiotics active against *Propionibacterium acnes* are frequently used as adjunctive therapy. Topical erythromycin and clindamycin have been shown to decrease *P. acnes* colonization and to lessen the percentage of free fatty acids in surface lipids.[52] For more severe acne, systemic antibiotics (erythromycin, clindamycin, or tetracycline) and retinoids (topical and systemic) are added to the therapeutic regimen. Topical antibiotic monotherapy is not recommended because of emergence of bacterial resistance and availability of superior topical alternatives.[53]

Impetigo

Impetigo is caused by *Streptococcus pyogenes* alone or in combination with *S. aureus*.[58,59] Topical therapy is sufficient for minor localized infection in a well child. Mupirocin has exquisite activity against these organisms and is the topical agent of choice for impetigo.[60] Retapamulin 1% ointment, approved by the FDA in 2007 for the treatment of impetigo secondary to *S. pyogenes* or methicillin-susceptible *S. aureus*, is a 1% semisynthetic pleuromutilin compound with in vitro activity against most gram-positive bacteria and anaerobes. Pleuromutilin may be active against some mupirocin-resistant *S. aureus* strains.[61] Systemic antibiotic therapy is required for a febrile or ill-appearing child (because of the possibility of bacteremia or toxin-mediated manifestations) or if there are multiple or deep lesions.

Prophylaxis and Treatment of Wounds

Although topical antibacterial agents are used commonly for the prophylaxis of minor cuts and abrasions, no study has demonstrated that their use prevents infection. In addition to topical antibiotics, antiseptic agents are used for cleansing and treating wounds. Antiseptic agents comprise a wide variety of substances that are applied to living tissues to inhibit or kill microorganisms. The mechanism of action of most agents is not understood clearly. Because methods of testing are not well standardized and it is difficult to make comparisons of antimicrobial activity between compounds, no quantification of the antimicrobial activity of antiseptic agents has been made. Table 294.8 lists antiseptics commonly used for the treatment of skin infections.[57,62–64]

TABLE 294.8

Antiseptics Used on Skin

Agent (Trade Name)	Spectrum of Activity[a]			Yeast	Adverse Effects
	Gram-Positive Organisms	Gram-Negative Organisms[b]	Anaerobes		
Acid electrolytic water (AEW)	S	S			
Benzalkonium chloride (Lanax, Zephiran, many brands)	S	S[c]		S	Nosocomial gram-negative bacilli and yeast infections from open contaminated solutions
Benzethonium chloride (many brands)	S	S	S		
Benzoyl peroxide (many brands)	S				Irritation and dryness
Chlorhexidine gluconate, solutions 2% and 4% (Hibiclens)	S	S		S	Possible CNS toxicity if broad application to neonate

Clioquinol (Vioform)	S				
Hexachlorophene (pHisoHex)	S				CNS toxicity if broad application to neonate
Phenol (Castellani Paint, Anbesol, Campho-Phenique)	S	S		S	Hyperbilirubinemia in neonates; ? carcinogenic potential
Povidone-iodine (Betadine)	S	S	S	S	Excessive area of application can cause thyroid dysfunction
Triple dye (brilliant green, proflavine hemisulfate, gentian violet)	S				Can be deleterious to wound healing
Triclosan	S				Limited against gram-negative bacilli; may lead to *Pseudomonas aeruginosa* overgrowth

[a] S, susceptible; blanks indicate resistance or insufficient data.

[b] Gram-negative organisms include *Haemophilus* spp., *Neisseria* spp., Enterobacteriaceae, and *Pseudomonas* spp.

[c] *Pseudomonas* is frequently resistant.

CNS, central nervous system.

Data from references 57, 62–64.

Topical agents such as mupirocin have been used intranasally in an attempt to eliminate colonization with *S. aureus.* Mupirocin is especially advantageous because of efficacy against methicillin-resistant *S. aureus* (MRSA). Unfortunately, increasing use has been associated with the emergence of mupirocin resistance and failure to eradicate community-acquired MRSA.[65,66] Dilute sodium hypochlorite (bleach) baths have been used, alone or concurrently with intranasal mupirocin, in attempt to decrease MRSA colonization, with variable outcomes.[67,68]

Therapy for Burns

Infections are a leading cause of death in burn victims who are successfully resuscitated. The burn wound is often the source of infection in these patients. Aggressive, early surgical debridement and wound closure, in combination with routine use of topical antimicrobial agents, have contributed immensely to prevention and control of burn wound sepsis. Burn wound infection is defined as bacterial invasion into the underlying viable tissue and usually correlates with more than 10^5 colony-forming units per gram of tissue. Topical antimicrobial agents do not sterilize the wound, but rather decrease the number of colonizing bacteria and the risk for deeper bacterial invasion into underlying viable tissue. Thus their major role is one of prophylaxis. For established burn wound sepsis, topical therapy is used in conjunction with aggressive surgical debridement and parenteral antibiotic therapy. Many topical agents are used, all differing in their antimicrobial spectrum of activity and side effects, but none is ideal. The characteristics of an ideal agent are listed in Box 294.1.

Box 294.1

Characteristics of an Ideal Topical Antimicrobial Agent

General

Painless on application

Nonallergenic

No systemic absorption

Long lasting

Ease of use

Inexpensive

Pertinent to Burn Wounds

Penetrates burn wounds to a sufficient depth

Prevents desiccation

Does not impair the ability to examine wounds

Controls bacterial proliferation

Does not promote bacterial resistance

Does not inhibit re-epithelialization

Does not injure viable cells

The most commonly used agents are shown in Table 294.9.[69–91] The agent used most widely has been silver sulfadiazine because of its broad antibacterial spectrum and relatively minor side effects. Other nonconventional topical agents such as acetic acid, formalin, and honey are used occasionally.[36,37,92–96] To some extent, all topical antimicrobial agents inhibit the rate of wound epithelialization, but on balance, their prophylactic efficacy against burn wound infection merits use.[97,98] Although susceptibility testing can be performed by several methods (most commonly the Nathan agar well diffusion assay), such methods are poorly standardized for topical antimicrobial testing and results have varied widely.[70,71,99–101] Selection of topical agents is based on known or expected colonizing organisms and their presumed susceptibilities, timing of injury, knowledge of organisms indigenous to the burn unit, and possible adverse reactions of agents. Occasionally, preparations of systemically administered antibacterial and antifungal agents are made extemporaneously for topical use when an infection is due to organism resistant to available topical agents or when cultured autografts are used because many routine preparations can be toxic to keratinocytes. Such use must be restricted and for short periods as resistance develops rapidly (precluding future use of that agent systemically).

TABLE 294.9

Topical Antimicrobial Agents Used in the Treatment of Burns

Agent (Trade Name)	Mechanism of Action	Antimicrobial Activity			
		Gram-Positive Organisms	Gram-Negative Organisms[a]	Anaerobes	Yeast
Acetic acid	Unknown	ND	*Pseudomonas aeruginosa*	ND	ND
Bacitracin, 400, 500 U/g (generic)	Inhibits early steps in peptidoglycan biosynthesis resulting in inhibition of cell wall synthesis; also changes cell membrane permeability	+++ (Group B *Streptococcus* R)	+	++	–
Cerium	Unknown	+++	+++	ND	+++

nitrate, 2.2%					
Chlorhexidine	Unknown	+++	+++	ND	+
Fusidic acid, 2% (Fucidin)	Inhibits protein synthesis	+++	+ (Enterobacteriaceae, *Pseudomonas* spp. R)	++	−
Gentamicin, 0.1% (Garamycin)	Inhibits protein synthesis	+ (Synergy for *Staphylococcus aureus* and *Enterococcus* spp.)	+++	−	−
Mafenide acetate, 11.1% cream, 5% solution (Sulfamylon)	Unknown	+	+++	+++	+
Mupirocin, 2% (Bactroban)	Inhibits protein synthesis by irreversibly binding to bacterial isoleucyl transfer RNA synthesis	+++	+/− (*Pseudomonas* spp. R)	+/−	−
Neomycin, 3.5 mg/g	Inhibits protein synthesis	+	++ (*Pseudomonas* spp. R)	−	−
Nitrofurazone, 0.2% cream, solution (Furacin)	Inhibits several bacterial enzymes involved in carbohydrate metabolism	+++	+++	++	−
Polymyxin B, 5000, 10,000 U/g	Attaches to cell membrane, with disruption of osmotic properties leading to cell death	−	+++ (*Proteus* spp. R; *Serratia* spp. R)	+/− (*Bacillus fragilis* R)	+/− (In high concentratio
Povidone-iodine, 5% cream, 10%	Unknown	+++	+++	++	++

ointment (Betadine)					
Silver nitrate, 0.5% solution	Silver ion inhibits DNA replication; modifies cell membrane	+	++	+	+
Silver sulfadiazine, 1% cream (Silvadene, Thermazene)	Silver ion inhibits DNA replication; modifies cell membrane	++	+++	++	++

[a]Gram-negative organisms include *Haemophilus* spp., *Neisseria* spp., Enterobacteriaceae, and *Pseudomonas* spp., unless otherwise specified.

+++, excellent activity and spectrum; ++, good activity and spectrum; +, fair activity and spectrum; −, no activity; MRSA, methicillin-resistant *Staphylococcus aureus;* ND, no or limited data; R, resistant.

Data from references 36, 37, 69–91.

The toxicity of antibiotics on cultured skin and skin substitutes varies extensively, and the choice of agents should be based on the manufacturer's guidelines and the antimicrobial susceptibility of the organisms isolated.

295

Antiviral Agents

David W. Kimberlin

In 1963, idoxuridine became the first antiviral compound to be licensed by the US Food and Drug Administration (FDA) for the topical treatment of herpes simplex virus (HSV) keratitis. This was followed shortly by licensure of amantadine in 1966 as the first systemic antiviral compound for the treatment of influenza A infection. During the 1970s, only vidarabine (1976) received licensure for the systemic treatment of HSV central nervous system (CNS) infections. The licensure of acyclovir in 1982 opened the field of clinical antiviral drug intervention and heralded the era of rapid development of new drugs.

In addition to antiretroviral drugs for the treatment of the human immunodeficiency virus (HIV), three additional non-HIV antiviral drugs were licensed in the 1980s: trifluridine (1980), ribavirin (1985), and interferon (1986). Ten non-HIV antiviral drugs were licensed in the 1990s: foscarnet (1991), rimantadine (1993), ganciclovir (1994), famciclovir (1994), valacyclovir (1995), topical penciclovir (1996), cidofovir (1996), palivizumab (1998), zanamivir (1999), and oseltamivir (1999). Lamivudine, which was approved originally as an HIV medication, was licensed for the treatment of chronic hepatitis B virus (HBV) infection in 1998.

Fewer new antiviral agents were brought to market in the first decade of the 21st century, and all except valganciclovir were for the treatment of hepatitis B: valganciclovir (2001), tenofovir disoproxil fumarate (2001), adefovir dipivoxil (2002), pegylated interferon (2003), entecavir (2005), and telbivudine (2006). Since 2010, nine non-HIV antiviral drugs have been licensed for use in the

United States, eight of which were for the treatment of hepatitis C: boceprevir (2011), dasabuvir (2014), ledipasvir (2014), ombitasvir (2014), paritaprevir (2014), simeprevir (2013), sofosbuvir (2014), and telaprevir (2011) for hepatitis C, and peramivir (2014) for influenza.

Many of the hepatitis C drugs are used in fixed combinations (e.g., sofosbuvir plus ledipasvir [Harvoni]); ombitasvir, paritaprevir, and ritonavir copackaged with dasabuvir [Viekira Pak]) and are discussed as such in this chapter, although none currently has been approved for use in children. The pace of development of more potent hepatitis C antiviral agents has been rapid, rendering first-generation products obsolete. The products that are no longer recommended for the treatment of hepatitis C (e.g., boceprevir, telaprevir) are not discussed.

Approved antiviral agents have demonstrated efficacy in the treatment of infections caused by HSV, cytomegalovirus (CMV), varicella-zoster virus (VZV), HIV, respiratory syncytial virus (RSV), influenza A and B, hepatitis B and C, human papillomavirus (HPV), and Lassa virus.[1] Major sites of action of antiviral agents are listed in Table 295.1, with selected antiviral drugs for specific viruses given in Table 295.2. Mechanisms of antiviral resistance are presented in Table 295.3.

TABLE 295.1

Major Sites of Action of Antiviral Agents

Major Site of Action	Antiviral Agent
Viral entry, adsorption, penetration, or uncoating	Amantadine
	Rimantadine
Transcription or replication of viral genome	Acyclovir or valacyclovir
	Adefovir dipivoxil
	Cidofovir
	Dasabuvir
	Entecavir
	Famciclovir or penciclovir
	Foscarnet
	Ganciclovir or valganciclovir
	Lamivudine
	Paritaprevir
	Ribavirin
	Simeprevir
	Sofosbuvir
	Telbivudine
	Tenofovir
	Trifluridine
	Vidarabine

Viral assembly, release, or de-aggregation	Ledipasvir
	Ombitasvir
	Oseltamivir
	Peramivir
	Zanamivir

TABLE 295.2

Selected Antiviral Treatment Options, by Virus

Virus	Antiviral Drugs Indicated for Management
Cytomegalovirus	Ganciclovir
	Valganciclovir
	Foscarnet
	Cidofovir
Hepatitis B	Entecavir
	Tenofovir
	Lamivudine
	Telbivudine
	Adefovir
Hepatitis C	Sofosbuvir-ledipasvir
	Ombitasvir-paritaprevir/ritonavir copackaged with dasabuvir
	Sofosbuvir-ribavirin
	Sofosbuviror-simeprevir
Herpes simplex virus	Acyclovir
	Valacyclovir
	Famciclovir
	Penciclovir
	Foscarnet
	Cidofovir
Influenza A and B	Oseltamivir
	Zanamivir
	Peramivir
Lassa virus	Ribavirin
Human papillomavirus	Cidofovir
Respiratory syncytial virus	Ribavirin
Varicella-zoster virus	Acyclovir
	Valacyclovir
	Famciclovir
	Penciclovir
	Foscarnet

TABLE 295.3

Mechanisms of Antiviral Resistance

Antiviral	Viruses	Mechanism of Resistance	Clinical Correlates of Resistance	Alternative Antiviral Agents
Acyclovir **Valacyclovir**	HSV, VZV	Usually due to mutations in thymidine kinase gene,	Persistent or progressive infection due to resistant strains isolated from patients	Foscarnet

		resulting in absent or altered thymidine kinase; rarely due to mutation in DNA polymerase gene	with severely compromised immunity (e.g., bone marrow transplant recipients, those with AIDS); isolates of HSV from healthy people described in those receiving long-term suppressive therapy	
Amantadine **Rimantadine**	Influenza A	Mutation in RNA sequence encoding for M2 protein transmembrane domain	Usually recovered from drug recipients within 2 days of starting therapy and their infected household contacts; clinical relevance undefined	Oseltamivir Zanamivir
Cidofovir	CMV, HSV	Mutation in DNA polymerase gene	Only rare clinical isolates reported	Foscarnet
Famciclovir **Penciclovir**	HSV, VZV	Usually due to mutations in thymidine kinase gene, resulting in absent or altered thymidine kinase; also can result from mutation in DNA polymerase gene	Persistent or progressive infection due to resistant strains isolated from patients with severely compromised immunity (e.g., bone marrow transplant recipients those with AIDS); isolates of HSV from healthy people described in those receiving long-term suppressive therapy	Foscarnet Acyclovir
Foscarnet	HSV, VZV, CMV	Mutations in viral DNA polymerase gene	Only rare clinical isolates have been reported	Acyclovir Cidofovir
Ganciclovir **Valganciclovir**	CMV	Decreased intracellular phosphorylation due to mutations in the CMV *ul97* gene with decreased expression of CMV phosphotransferase enzymes or mutation in viral DNA polymerase gene	Responsible for severe, rapidly progressive infection in patients with severely compromised immunity (e.g., bone marrow transplant recipients, those with AIDS)	Foscarnet Cidofovir
Lamivudine	HBV	Mutation in HBV polymerase gene	Reappearance of HBV DNA in serum after its initial disappearance, although most patients continue to have lower serum HBV DNA and ALT levels compared with pretreatment levels	Adefovir Entecavir

AIDS, acquired immunodeficiency syndrome; ALT, alanine transferase; CMV, cytomegalovirus; HBV, hepatitis B virus; HSV, herpes simplex virus; VZV, varicella-zoster virus.

Non-HIV antiviral small-molecule agents that are licensed by the FDA are the primary focus of this chapter. Interferons are a family of nonspecific regulatory proteins associated with a variety of antiviral, antiproliferative, and immunomodulating activities.[2,3] Their use largely is being supplanted by entecavir and tenofovir, and they have been completely replaced by small molecules in the management of hepatitis C. Interferons therefore are not addressed in detail. Monoclonal and polyclonal antibody preparations, also used in the treatment and prevention of viral infections, are discussed in pathogen-specific chapters and in Chapter 5.

Nucleoside and Nucleotide Analogues and Protease Inhibitors

Acyclovir and Valacyclovir

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Acyclovir (Zovirax) (i.e., acycloguanosine [ACV]) is a deoxyguanosine analogue with an acyclic side chain that lacks the 3′-hydoxyl group of natural nucleosides.[4] After preferential uptake by infected cells, acyclovir is monophosphorylated by virus-encoded thymidine kinase (TK). Subsequent diphosphorylation and triphosphorylation are catalyzed by host cell enzymes, resulting in acyclovir triphosphate concentrations that are 40 to 100 times higher in HSV-infected cells than in noninfected cells.[5]

Acyclovir triphosphate prevents viral DNA synthesis by inhibiting the viral DNA polymerase. In vitro, acyclovir triphosphate competes with deoxyguanosine triphosphate as a substrate for viral DNA polymerase. Because acyclovir triphosphate lacks the 3′-hydroxyl group required for elongation of the DNA chain, the growing chain of DNA is terminated. In the presence of the deoxynucleoside triphosphate complementary to the next template position, the viral DNA polymerase is functionally inactivated.[6] Acyclovir triphosphate is a much better substrate for the viral polymerase than for cellular DNA polymerase, resulting in little incorporation of acyclovir into cellular DNA. The higher concentration of the active triphosphate metabolite in infected cells plus the affinity for viral polymerases result in the low toxicity of acyclovir in noninfected host cells.

Acyclovir is most active in vitro against HSV, with activity against VZV being about 10-fold less but still substantial. Although

Epstein-Barr virus (EBV) has only minimal TK activity, EBV DNA polymerase is susceptible to inhibition by acyclovir triphosphate. EBV is moderately susceptible to acyclovir in vitro. Activity against CMV is limited because CMV does not encode TK, and CMV DNA polymerase is poorly inhibited by acyclovir triphosphate.

In vitro susceptibility of viruses to acyclovir depends on several factors, including the cell line used, inoculum, incubation conditions, and the specific assay system used. No standardized method of susceptibility testing is universally accepted, and wide disparities in specific inhibitory concentrations of antiviral agents therefore are reported. Given these limitations, the relative activity of an antiviral agent is more meaningful than the absolute inhibitory concentration. The relative activities of drugs used in the treatment of herpesvirus infections are summarized in Table 295.4.

TABLE 295.4

Relative in vitro Activity of Nucleoside Analogues Against Herpesviruses

Virus	Acyclovir	Penciclovir	Vidarabine	Foscarnet	Ganciclovir
HSV-1	+++	++	++	++	+++
HSV-2	+++	++	++	++	+++
VZV	+++	+++	++	++	++
CMV	+/−	+/−	+/−	++	++
EBV	+	−	−	+	++

CMV, cytomegalovirus; EBV, Epstein–Barr virus; HSV, herpes simplex virus; VZV, varicella-zoster virus; +++, high degree of activity; ++, moderate degree of activity; +, minimal degree of activity; +/−, minimal to no activity; −, no useful activity.

Resistance of HSV to acyclovir has long been recognized. In some referral centers, 5% to 14% of HSV isolates from immunocompromised patients are resistant.[7] Resistance can result from mutations in the viral thymidine kinase gene or the viral DNA polymerase gene. Although these acyclovir-resistant isolates exhibit diminished virulence in animal models, they can cause severe, progressive, debilitating mucosal disease and, rarely, visceral dissemination in HIV-infected patients.[8,9] Acyclovir-resistant strains of HSV also have been recovered from patients receiving cancer chemotherapy, bone marrow and solid-organ transplant recipients, children with congenital immunodeficiency syndromes, and neonates.[10,11] Although it is uncommon, genital herpes caused by acyclovir-resistant isolates has been reported in immunocompetent hosts, who usually have received chronic acyclovir therapy.[12]

Acyclovir-resistant strains of VZV are reported. Resistance is caused by the same mechanisms described for HSV isolates. Most acyclovir-resistant VZV strains have been isolated from HIV-infected children and adults who have had profound depletion of $CD4^+$ cells ($\leq 100/mm^3$) and prolonged acyclovir therapy.[13] Changes in the susceptibility of VZV isolates to acyclovir can develop after only 4 to 12 weeks.[10] Foscarnet is the drug of choice for HSV and VZV infections caused by acyclovir-resistant strains.[10]

Valacyclovir (Valtrex) is the L-valyl ester of acyclovir. After oral administration, valacyclovir is rapidly converted to acyclovir by first-pass metabolism in the liver.[14] Its mechanism of action, antiviral spectrum, and resistance are the same as those of its parent drug, acyclovir.

Pharmacokinetics.

Acyclovir is available as a topical formulation, in oral formulations (i.e., capsules, tablets, and suspension), and as a sterile powder for intravenous infusion. The topical formulation licensed in the United States is an ointment, whereas a cream is available in Europe. Although these topical products are not absorbed systemically, a substantial concentration of the drug reaches the basal epidermis in cutaneous infections. Only 15% to 30% of the oral formulations of acyclovir is absorbed; peak concentrations of approximately 0.5 μg/mL are attained 1.5 to 2.5 hours after a 200-mg dose.[4,15] Higher doses result in higher serum concentrations, and food does not alter the extent of absorption substantially. Steady-state concentrations of acyclovir after intravenous doses of 2.5 to 15 mg/kg range from 6.7 to 20.6 μg/mL. The disposition of acyclovir is not affected by the duration or frequency of dosing.

Systemically administered acyclovir is distributed widely, attaining high concentrations in the kidneys, lung, liver, heart, and skin vesicles; concentration attained in the cerebrospinal fluid (CSF) is approximately 50% that of plasma.[4] Acyclovir readily crosses the placenta and accumulates in breast milk. The rate of protein binding ranges from 9% to 33% and is independent of the plasma drug concentration. Less than 20% of acyclovir is metabolized to a biologically inactive metabolite; more than 60% of administered drug is excreted intact in the urine. The half-life of acyclovir is 2 to 3 hours in older children and adults and 2.5 to 5 hours in neonates with normal creatinine clearance (CrCl).[4] Elimination of acyclovir is prolonged in patients with renal dysfunction, with a half-life of approximately 20 hours in those with end-stage renal disease.[16] Dosage modifications are necessary for patients with CrCl values less than 50 mL/min.1.73 m^2. Dosing guidelines for various degrees of renal dysfunction are given in Table 295.5. Acyclovir is readily hemodialyzable. The mean plasma half-life in patients during hemodialysis is about 5 hours, requiring that patients receive an additional dose of acyclovir after each dialysis (Table 295.6).[17] The half-life of acyclovir is 13 to 18 hours during continuous ambulatory peritoneal dialysis (CAPD), and no supplemental dose is necessary after adjustment of the dosing interval.

TABLE 295.5

Dosage Adjustment of Acyclovir in Individuals With Renal Dysfunction

Creatinine Clearance (mL/min/1.73/m^2)	Suggested Modifications of Standard Intravenous Dose	Suggested Modification of Standard Oral Dose
>50	No modification necessary	No modification necessary
25–50	Maintain unit dose, but increase the dosing interval by 50%	No modification necessary
10–25	Maintain unit dose, but double the dosing interval	Maintain unit dose, but double the dosing interval
0–10	Reduce dose by 50% *and* double the dosing interval	Maintain unit dose, but triple the dosing interval

Data from Wagstaff AJ, Faulds D, Goa KL. Aciclovir: a reappraisal of its antiviral activity, pharmacokinetic properties and therapeutic efficacy. Drugs 1994;47:153–205; Laskin OL, Longstreth JA, Whelton A, et al. Effect of renal failure on the pharmacokinetics of acyclovir. Am J Med 1982;73:197–201.

TABLE 295.6

Dosage Adjustments of Antiviral Agents for Renal Dysfunction[a]

Antiviral Agents	Creatinine Clearance–Necessitating Dose Adjustment (mL/min/1.73 m^2)	Need for Supplementary Dose After Hemodialysis
Acyclovir	<50	Yes
Adefovir	<50	No[b]
Amantadine	<80	No
Entecavir	<50	No[b]
Famciclovir (for VZV)	<60	Yes

Famciclovir (for HSV)	<40	Yes
Foscarnet	<100	Yes
Ganciclovir	<80	Yes
Lamivudine	<50	Unknown
Oseltamivir	<30	Unknown
Peramivir	<50	Yes
Ribavirin	—	No
Rimantadine	—	No

[a] Cidofovir dosing must be adjusted for renal dysfunction but is based on changes in the creatinine level from baseline.

[b] Administer recommended dose at the appropriate interval after hemodialysis.

HSV, herpes simplex virus; VZV, varicella-zoster virus.

After oral administration of valacyclovir, rapid and complete conversion to acyclovir occurs with first-pass intestinal and hepatic metabolism. The bioavailability of valacyclovir in adults exceeds 50%, which is three to five times greater than that of acyclovir.[18] The peak serum concentration, which is attained about 1.5 hours after a dose has been given, is proportional to the amount of drug administered, ranging from 0.8 to 8.5 μg/mL for doses of 100 to 2000 mg.[19] The area under the drug concentration–time curve (AUC) approximates that seen after intravenous acyclovir. All other pharmacokinetic characteristics are similar to those of acyclovir.

Valacyclovir oral suspension has been studied in children 1 month to 12 years of age.[20] Bioavailability is estimated to be 45% to 51% in all age groups except those 3 through 5 months of age, in whom the bioavailability is about 22%. Approximate dose proportionality in the maximal concentration observed (C_{max}) and AUC occurs across the 10- to 25-mg/kg dose range (i.e., dose normalized differences usually within ≤30%), with the exception of children 2 through 5 years of age, for whom a modest increase in dose from 20 to 25 mg/kg is associated with almost doubling the C_{max} and AUC values.[20]

Toxicity and Drug Interactions.

Acyclovir consistently has demonstrated a favorable safety profile. The topical formulation can cause transient burning, especially when applied to ulcerated mucosal lesions. Oral acyclovir sometimes is associated with mild gastrointestinal upset, rash, and headache, but even long-term administration usually is well tolerated. Intravenous acyclovir usually is well tolerated. Because of its alkalinity (pH 9–11), extravasation of drug at the injection site can cause severe inflammation, phlebitis, and sometimes a vesicular eruption leading to cutaneous necrosis. Reversible nephrotoxicity occurs if acyclovir is given by rapid intravenous infusion or to patients who are poorly hydrated or who have preexisting renal compromise. Obstructive nephropathy results from the formation of acyclovir crystals that precipitate in renal tubules. In one study, acute renal insult occurred in 35% of patients beyond the neonatal period who were given acyclovir intravenously.[21] Nephrotoxicity was associated with a dose exceeding 15 mg/kg, age older than 8 years, and BMI greater than 19 kg/m^2. Other reported side effects of intravenous acyclovir include rash, sweating, nausea, headache, hematuria, and hypotension. The use of high doses of intravenous acyclovir (60 mg/kg/day) for the treatment of neonatal disease has been associated with neutropenia in some patients.[22]

The most serious side effect of acyclovir is neurotoxicity. When it occurs, lethargy, confusion, hallucinations, tremors, myoclonus, seizures, extrapyramidal signs, and changes in state of consciousness develop within the first few days of starting therapy. Neurotoxicity usually occurs in patients with compromised renal function who attain high serum concentrations of the drug.[23] Other risk factors can include concurrent administration of interferon or intrathecal methotrexate. Neurotoxic manifestations usually resolve spontaneously within several days after the discontinuation of acyclovir; hemodialysis may be useful in severe cases associated with high serum concentrations of the drug.

Although acyclovir is mutagenic at high concentrations in some in vitro assays, it is not teratogenic in various animal models. Acyclovir is not recommended for use in pregnant women, but limited data suggest that such use is not associated with congenital defects or other adverse gestational outcomes.[24] The finding of neutropenia in infants given acyclovir orally to suppress HSV reactivation after neonatal infection is not well explained.

Limited adverse drug interactions have been reported. Subjects being treated with zidovudine plus acyclovir can develop severe somnolence and lethargy. The likelihood of renal toxicity is increased when acyclovir is administered with nephrotoxic drugs such as cyclosporine and amphotericin B. Concomitant administration of probenecid decreases renal clearance of acyclovir and prolongs its half-life; conversely, acyclovir can decrease the clearance of drugs such as methotrexate that are eliminated by active renal secretion.

The profiles of adverse effects and potential drug interactions observed with valacyclovir therapy are the same as those observed with acyclovir. Neurotoxicity has not been reported in humans, although it has been observed in animal models.[14] Manifestations resembling thrombotic microangiopathy have been described in patients with advanced HIV disease receiving high doses of valacyclovir, but the coadministration of multiple medications makes the establishment of a causal relationship difficult.[25]

Clinical Uses and Dosage.

Acyclovir is effective for the treatment of infections caused by HSV and VZV in immunocompetent and immunocompromised hosts.[26] Table 295.7 outlines the infections for which acyclovir is effective, the recommended dosage, and magnitude of anticipated benefits. Unless otherwise stated, the anticipated benefits of acyclovir therapy are based on the results of randomized, controlled trials.

TABLE 295.7

Indications for Acyclovir Use

Infection	Dosage	Anticipated Benefits	Factors Favoring Beneficial Effect of Therapy	Strength of Indication
Initial genital HSV	15 mg/kg/day IV in 3 divided doses for 5–7 days *or* 40–80 mg/kg/day (maximum: 1000 mg/day) PO in 3–4 divided doses for 5–10 days[a]	4–12-day reduction in duration of viral shedding, 3–12-day reduction in time to healing, and 1–10-day reduction in duration of pain; therapy is not associated with reduced frequency of subsequent recurrences[36–38]	Intravenous, rather than oral, therapy; therapy for primary, rather than less severe first episode, nonprimary infections	++
Recurrent genital HSV	1000 mg/day in 5 divided doses for 5 days *or* 1600 mg/day in 2 divided doses for 5 days *or* 2400 mg/day in 3 divided *or* doses for 2 days[a]	1–2-day reduction in duration of viral shedding and time to healing; no difference in duration of pain or frequency of subsequent recurrences[41,47,344]	Initiation during prodromal phase of infection	+/−

Primary HSV labialis	2400 mg/m^2/day PO in 4 divided doses for 10 days	6-day reduction in the duration of viral shedding and 2–4-day reduction in the duration of drooling, gum swelling, and healing of oral and cutaneous lesions[46]	Initiation within 4 days of onset of signs of infection	++
Recurrent HSV labialis	1000 mg/day PO in 5 divided doses for 5 days	0.5–2-day reduction in the duration of pain and time to healing[45]	Initiation during prodromal or erythema stage	+/−
Mucocutaneous HSV in compromised hosts	30 mg/kg/day IV in 3 divided doses for 7–14 days	60–80% reduction in the duration of viral shedding, 30–60% reduction in healing time and the duration of pain[35]	Recovery of immune function	+++
Viscerally disseminated HSV in pregnant women and transplant recipients	30 mg/kg/day IV in 3 divided doses for 7–14 days	Improved likelihood of recovery based on anecdotal reports, rather than controlled trials[33,34]	—	+++
HSV encephalitis	30–45 mg/kg/day IV in 3 divided doses for 14–21 days	Reduced mortality and improved long-term neurologic outcome[27]	High (>6) Glasgow Coma Score at time of initiation of therapy; young age (<30 years)	++++
Neonatal HSV	60 mg/kg/day IV in 3 divided doses for 14 (SEM) to 21 (CNS, disseminated) days	Reduced mortality and improved long-term neurologic outcome[21,29]	Infection limited to the skin, eye, and mucosal membranes; absence of seizures at initiation of therapy for CNS infection	++++
Primary varicella in normal children, adolescents, and adults	80 mg/kg/day (maximum: 3200 mg/day) PO in 4 divided doses for 5 days	1–3-day reduction in new lesion formation and fever; reduced maximal number of lesions[48–50]	Initiation of therapy within 24 hours of onset of infection; older subjects and secondary cases in household benefit more than younger subjects and those with community-acquired infections	+/++
Disseminated varicella in previously healthy subjects	30 mg/kg/day IV in 3 divided doses for 7–10 days	Improved likelihood of recovery based on anecdotal reports rather than controlled trials[345]	—	+++
Zoster in normal hosts	80 mg/kg/day (maximum: 4000 mg/day) PO in 5 divided doses for 5–7 days	Reduced time to healing of skin lesions, duration of acute pain, and duration of viral shedding[52,53]	Initiation of therapy within 24–48 hours of onset of infection	+
Zoster	80 mg/kg/day	Reduced incidence of	—	++

ophthalmicus in normal hosts	(maximum: 4000 mg/day) PO in 5 divided doses for 5–7 days	keratitis and anterior uveitis[44]		
Primary varicella in compromised hosts	30 mg/kg/day IV in 3 divided doses for 7–10 days	Reduced incidence of cutaneous and visceral dissemination; reduced duration of lesion formation and time to healing[29,30]	Initiation of therapy within 24–48 hours of onset of infection and mild degree of immunologic dysfunction	++++
Zoster in compromised hosts	30 mg/kg/day IV in 3 divided doses for 7–10 days	Reduced risk of cutaneous dissemination and visceral complications[28,32]	Initiation of therapy within 24–48 hours of onset of infection and mild degree of immunologic dysfunction	++++

[a] Topical acyclovir is not recommended because its effects on duration of viral shedding, pain, and lesions are much less than those of systemic therapy in patients with primary infections.

CNS, central nervous system; HSV, herpes simplex virus; IV, intravenous; PO, orally; SEM, localized infection with disease limited to skin, eye, or mouth; +/−, benefit is limited and therapy usually not indicated; +, benefit is consistent but limited, and costs of therapy should be weighed against small amount of anticipated benefit and the decision to treat individualized; ++, therapeutic benefit usually favors treatment; +++, therapy indicated, although supporting data not definitive; ++++, therapy is clearly indicated and is based on the results of controlled clinical trials.

Therapy is indicated for life-threatening infections and for disease associated with severe morbidity and death, such as HSV encephalitis, neonatal HSV infections, and VZV infections in immunocompromised hosts.[21,27–32] Acyclovir therapy also is indicated for mucocutaneous HSV infections in immunocompromised hosts and for disseminated HSV and VZV infections in otherwise normal hosts, including pregnant women.[33–35] Acyclovir is effective for the treatment of symptomatic primary genital HSV infections,[36–39] reducing the median duration of virus shedding, pain, and length of time to complete healing.[40]

Intravenous and oral acyclovir therapies are almost equally efficacious; topical treatment provides less benefit. Neither intravenous nor oral treatment with acyclovir for primary or recurrent genital HSV disease reduces the frequency of recurrences.[41–43] Acyclovir probably reduces the ocular morbidity of zoster ophthalmicus.[44] The advantages of treating previously healthy individuals with herpes labialis,[45,46] recurrent genital herpes,[39,41,47] varicella,[48–51] and herpes zoster[52,53] are less dramatic, and the treatment of these patients should be individualized.

Favorable effects of therapy are more likely when acyclovir is begun soon after the onset of infection. For example, previously healthy people with primary varicella may benefit only if acyclovir is begun within 24 hours of appearance of the first cutaneous lesions.[48–50] Benefit, however, can be observed in the treatment of severe, life-threatening infections caused by HSV and VZV even if acyclovir is commenced several days after the onset of infection, provided that irreversible damage has not occurred.

Indications for prophylactic acyclovir therapy are summarized in Table 295.8. Prophylactic acyclovir is almost exclusively used for the suppression of HSV infections; its efficacy for CMV infections is inferior to that of ganciclovir.[54] The most frequent indication for long-term prophylactic therapy is in patients with frequently recurrent genital infections[39] in whom daily administration of acyclovir reduces the frequency of recurrences by at least 75%. Acyclovir has been shown to maintain a high degree of efficacy and little toxicity even after more than 5 years of continuous suppressive therapy.[55]

TABLE 295.8

Indications for Prophylactic Antiviral Therapy

Antiviral Agent	Clinical Indication	Expected Effect	Dosage
Acyclovir	Frequently recurrent genital HSV	70–90% reduction in frequency of clinical episodes of infection[55,61,62]; frequency of asymptomatic shedding also reduced, but not eliminated[346]	Start with 1000 mg/day in divided doses and slowly reduce to minimum effective dose; attempt withdrawal after 6–12 months; if symptoms recur, restart therapy
	Frequently recurrent HSV labialis	53% reduction in number of clinical recurrences[63]	400 mg bid for 4 months
	Skiers with histories of sun-induced recurrences of HSV labialis	73% reduction in risk of recurrence[60]	400 mg bid for 1 week
	Suppressive therapy after treatment of acute neonatal HSV disease	30% reduction in cutaneous recurrence (all disease categories); improved neurodevelopmental outcomes (CNS category)[66]	300 mg/m^2/dose tid for 6 months; monitor absolute neutrophil counts at 2 and 4 weeks, then monthly during therapy
	Reactivations of HSV associated with serious systemic complications such as erythema	Reduction in the frequency of serious complications associated with HSV infection	Use is supported by theoretical benefit and anecdotal reports, rather than controlled trials[61,65]; dosage is empiric

	multiforme, aseptic meningitis, and eczema herpeticum		
	Dermabrasion of facial skin or surgery involving the trigeminal ganglion in patients previously infected with HSV-1	Reduction in the frequency of postoperative outbreaks of herpes labialis[61,65]	Use is supported by theoretical benefit and anecdotal reports, rather than controlled trials; dosage is empiric
	HSV-seropositive persons undergoing bone marrow or solid-organ transplantation or induction chemotherapy for hematologic malignancy	50–60% decrease in number of herpetic recurrences during the time of drug administration[61]	500–750 mg/m^2/day begun before transplantation or induction chemotherapy and continued for about 6 weeks thereafter; intravenous therapy initially and oral therapy when tolerated
	CMV-seropositive persons undergoing bone marrow or solid-organ transplantation	As much as 50% reduction in the frequency of CMV infection and disease in CMV-seropositive recipients[347] and, to a lesser extent, in recipients at risk for primary infection[348]; however, ganciclovir is drug of choice[60]	1500 mg/m^2/day begun before transplantation and continued for 1–3 months thereafter; intravenous therapy initially, and oral therapy when tolerated
Ganciclovir	CMV-seropositive solid-organ transplant recipients	Reduction in frequency of CMV disease	10 mg/kg/day in 2 divided doses, started several days before transplantation and continued for 2–3 weeks after transplantation; 5 mg/kg/day in single dose thereafter
	CMV-seropositive renal or liver transplant recipients beginning OKT3 suppressive therapy	Reduction in frequency of CMV disease	10 mg/kg/day in 2 divided doses for 2–3 weeks after OKT3 initiated
	Bone marrow transplant recipients with positive CMV surveillance culture	Reduction in frequency of CMV disease	10 mg/kg/day in 2 divided doses for 2–3 weeks after transplantation; 5 mg/kg/day in single dose thereafter

CMV, cytomegalovirus; CNS, central nervous system; HSV, herpes simplex virus.

The use of prophylactic acyclovir therapy in pregnant women has been explored in several small studies,[56–58] but the numbers of patients evaluated are insufficient to prove definitively its safety or efficacy in this population. Neonatal HSV disease in babies born to women receiving antiviral suppression is reported.[59] Brief courses of acyclovir can be given to HSV-1–infected patients to suppress reactivation of HSV that predictably follows stimuli such as exposure to ultraviolet radiation[60] or facial surgery.[61] Longer courses can be given to those with frequently recurrent oral HSV infections,[55,61–63] and to people after ocular HSV disease to prevent recurrence.[64]

Prophylactic acyclovir has proved to be a useful strategy for postponing the inevitable reactivation of HSV infection in HIV-infected people with severe immunosuppression.[61] Anecdotal data suggest that prophylactic acyclovir can reduce the frequency of attacks of erythema multiforme temporally related to HSV.[65]

Data published in 2011 describe the benefit of oral acyclovir suppressive therapy after parenteral acyclovir therapy for acute neonatal HSV disease.[66] The National Institute of Allergy and Infectious Diseases (NIAID) Collaborative Antiviral Study Group conducted a placebo-controlled evaluation of 6 months of oral acyclovir suppression after neonatal herpes infection. Subjects with neonatal HSV CNS disease who were randomized immediately at the conclusion of intravenous therapy to oral acyclovir for suppression had more favorable neurodevelopmental outcomes at 12 months of age compared with those in whom antiviral suppression was delayed until cutaneous recurrences occurred. Suppressive oral acyclovir therapy also delayed the development of cutaneous recurrences in all categories of neonatal HSV disease.[66]

The indications for valacyclovir therapy are the same as those for acyclovir.[39,67–69] Adult treatment doses are 1 g given orally three times daily for 7 days for herpes zoster in patients older than 50 years of age; 1 g given orally twice daily for 10 days for first-episode genital herpes; 500 mg given orally twice daily for 3 days for episodic treatment of recurrent genital HSV disease; 1 g given orally once daily for suppression of recurrent genital HSV; and 2 g given orally twice daily for 1 day for recurrent herpes labialis (≥12 years of age). The efficacy of valacyclovir has been demonstrated in the short-term treatment of recurrent herpes labialis (2 g PO bid for 1 day)[70] and in the suppression of recurrent herpes labialis (500 mg once daily).[71]

In children, valacyclovir dosing is 20 mg/kg per dose (dose not to exceed 1 g) administered three times daily (for VZV) or twice daily (for HSV).[20] In the United States, valacyclovir is licensed for the treatment of pediatric patients with orolabial HSV recurrences ≥12 years of age) and chickenpox (2–17 years of age). Although comparative data from controlled studies are limited, valacyclovir may be advantageous in treating infections caused by viruses that are less sensitive to acyclovir than HSV (i.e., VZV and CMV).

Adefovir Dipivoxil

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Adefovir dipivoxil (Hepsera) is the oral prodrug of adefovir, which is an acyclic nucleotide analogue of deoxyadenosine-5′-monophosphate (dAMP).[72,73] Conversion of the prodrug to the active adefovir diphosphate is accomplished by cellular adenylate kinase. Adefovir diphosphate then acts as a competitive inhibitor of deoxyadenosine triphosphate for viral DNA polymerase, resulting in DNA chain termination after its incorporation in HBV DNA.[72,73] In addition to HBV, adefovir diphosphate competitively inhibits deoxyadenosine triphosphate as a substrate for HIV-1 reverse transcriptase, resulting in chain termination after its incorporation in HIV DNA.[74–76] In vitro, adefovir has an additive effect when combined with lamivudine, entecavir, or telbivudine.[77]

Resistance to adefovir is a limiting factor of prolonged use. The N236T mutation and the A181V mutation in the HBV polymerase confer in vitro and in vivo antiviral resistance to adefovir diphosphate.[78] Rates of resistance to adefovir at 1, 2, 4, and 5 years are 0%, 3%, 18%, and 29%, respectively.[79] HBV strains with the A181V mutation also are resistant to lamivudine.

Pharmacokinetics.

Adefovir dipivoxil is absorbed rapidly after oral administration. After a single oral dose, the bioavailability is about 59%.[80] Food does not substantially impact absorption of adefovir dipivoxil.[80] Half-life at steady state is approximately 7 hours. After absorption, adefovir dipivoxil is cleaved to adefovir by extracellular esterases.[80] Adefovir then is phosphorylated to the active moiety adefovir diphosphate by cellular adenylate kinase. The estimated intracellular half-life of adefovir diphosphate is 16 to 18 hours.[75] Adefovir is excreted renally as unchanged drug by tubular secretion and glomerular filtration.

Dosing in patients with baseline CrCl values less than 50 mL/min requires adjustment in the dosing interval.[80] The dose of adefovir dipivoxil does not need to be adjusted in patients with hepatic impairment.

Toxicity and Drug Interactions.

Adefovir usually is well tolerated over prolonged periods of administration.[79,81] In randomized, controlled trials, diarrhea, headache, and abdominal pain occurred slightly more frequently in adefovir-treated patients than placebo-treated patients.[82,83] Long-term administration may result in nephrotoxicity, but the risk for patients with adequate renal function is low.[79,84] In vitro, adefovir does not inhibit cytochrome P450. No clinically relevant drug interactions have been reported in clinical trials.[80]

Clinical Uses and Recommended Doses.

Adefovir has been studied in children with HBV infection, and is approved for use in patients ≥12 years of age. Adefovir is the preferred oral treatment option for children 12 through 15 years of age, after which they can be treated with entecavir.[85] In HBeAg-positive children from 2 through 17 years of age with alanine aminotransferase (ALT) values at least 1.5 times the upper limit of normal, adefovir therapy resulted in undetectable HSV DNA and normalization of ALT levels in 12- through 17-year-old patients but not in the 2- through 11-year-old patients.[86] In this trial of 173 children, no adverse effect associated with adefovir was identified,[86] and the drug was well tolerated in all age groups.

With a greater number of approved anti-HBV treatment options for adults, adefovir is not as effective as other antiviral agents and is no longer favored for the treatment of chronic HBV infection. In adults, adefovir therapy is associated with a 12% rate of HBeAg seroconversion, 21% rate of undetectable serum HBV DNA, and 53% rate of histologic improvement in HBeAg-positive patients after 1 year of therapy.[83] Once seroconversion occurs, it is sustained in 91% of patients.[87,88] In adults, persistence of high levels of HBV DNA after 48 weeks of adefovir therapy predicts the emergence of resistance.[79]

The optimal duration of adefovir treatment of children is unknown. In the pivotal pediatric study,[86] children were treated for 48 weeks. For those who did not seroconvert during this time, continued treatment for up to 2 years was provided. Results of this extended therapy have not been reported. Children with HBeAg-positive chronic HBV infection should continue on treatment for at least 6 months after seroconversion.[85] Monitoring for several months after cessation of therapy is recommended because posttreatment flares have been reported in adults.[80,89] The recommended dose of adefovir dipivoxil for chronic hepatitis B patients 12 years of age or older with adequate renal function is 10 mg, taken orally once daily without regard to food.

Cidofovir

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Cidofovir (Vistide), or (5)-1-(3-hydroxy-2-(phosphonylmethoxy)-propyl)cytosine (HPMPC), is a novel acyclic phosphonate nucleotide analogue. Cidofovir has a mechanism of action that is similar to that of the nucleoside analogues, such as acyclovir and ganciclovir. In its native form, however, cidofovir already has a single phosphate group attached, and viral enzymes are not required for the initial phosphorylation of the drug. Cellular kinases sequentially attach two additional phosphate groups, converting cidofovir to its most active form. The active compound is a competitive inhibitor of DNA polymerase.[90] Although cidofovir is taken up by virus-infected and uninfected cells, the active form of the drug exhibits a 25-fold to 50-fold greater affinity for the viral DNA polymerase compared with the cellular DNA polymerase, selectively inhibiting viral replication.[90,91] Incorporation into the growing viral DNA chain results in reductions in the rate of DNA synthesis.

Cidofovir has activity against HSV and CMV. Because of its unique phosphorylation requirements for activation, the drug usually maintains activity against acyclovir- and foscarnet-resistant HSV isolates and against ganciclovir- and foscarnet-resistant CMV mutants. Cidofovir exhibits marked activity against CMV, with inhibitory concentrations of 0.1 μg/mL for susceptible clinical isolates.[92] Although cidofovir is less potent in vitro against HSV than is acyclovir, its favorable pharmacokinetic profile increases its anti-HSV activity. Cidofovir also has in vitro activity against VZV, EBV, human herpesvirus 6, human herpesvirus 8, polyomaviruses, orthopoxviruses, adenovirus, BK virus, and HPV.

Only a small number of cidofovir-resistant CMV isolates has been described. Some also are resistant to ganciclovir because of mutations in the DNA polymerase gene, but they remain sensitive to foscarnet.[93–95]

Pharmacokinetics.

After intravenous administration, the plasma half-life is 2.6 hours, although cidofovir persists in cells for prolonged periods.[96] Active intracellular metabolites of cidofovir have half-lives of 17 to 48 hours.[91] This prolonged intracellular activity allows for an intermittent dosing schedule that is attractive compared with that for ganciclovir or foscarnet. About 90% of drug is excreted in the urine, primarily by renal tubular secretion.[97,98]

Toxicity and Drug Interactions.

Nephrotoxicity is the principal adverse event associated with systemic administration.[97,98] Cidofovir concentrates in renal cells in amounts 100 times greater than in other tissues, producing severe nephrotoxicity involving the proximal convoluted tubule if concomitant hydration and administration of probenecid are not employed.[99] Renal toxicity manifests as proteinuria and glycosuria.[100] To decrease the potential for nephrotoxicity, aggressive intravenous prehydration and coadministration of probenecid are required with each cidofovir dose. Within 48 hours before delivery of each dose of cidofovir, serum creatinine and urine protein concentrations must be determined and the dose adjusted if indicated. Cidofovir should not be administered concomitantly with other nephrotoxic agents. Cidofovir is contraindicated in patients with a serum creatinine level greater than 1.5 mg/dL, a calculated CrCl of 55 mL/min or lower, or a urine protein level of at least 100 mg/dL (i.e., ≥2+ proteinuria). The maintenance dose of cidofovir must be reduced from 5 to 3 mg/kg for an increase in serum creatinine of 0.3 to 0.4 mg/dL above baseline. Cidofovir therapy must be discontinued if the serum creatinine level increases by at least 0.5 mg/dL above baseline.

Cidofovir can have other adverse effects. In animal studies, cidofovir has been carcinogenic and teratogenic and has caused hypospermia.

Because of poor oral bioavailability (2%–26%),[101] cidofovir can be administered only intravenously or topically. Intravitreal administration has been associated with ocular hypotony.

Clinical Uses and Recommended Doses.

Cidofovir has been evaluated for the treatment of CMV retinitis in patients with acquired immunodeficiency syndrome (AIDS).[102,103] Therapy delays progression of retinal disease. In one study, patients who had failed or were intolerant of traditional therapy (i.e., ganciclovir or foscarnet) were treated with a 2-week induction course of cidofovir (5 mg/kg administered weekly) followed by randomization to maintenance with a dose of 5 mg/kg or 3 mg/kg every other week.[102] At the higher maintenance dose of cidofovir, disease progression was delayed for 115 days, compared with 49 days in the lower-dose cohort. Cidofovir also has been used successfully in the management of disease caused by acyclovir-resistant HSV isolates.[99]

The safety and efficacy of cidofovir in children have not been studied. The use of cidofovir in children with AIDS warrants caution because of the risk of long-term carcinogenicity and reproductive toxicity.

Intralesional injection of cidofovir has been reported in several small, uncontrolled studies of patients with laryngeal papillomatosis caused by HPV infection.[104,105] Some patients have experienced dramatic improvement in their disease, although the anecdotal nature of the trials prevents definitive conclusions regarding efficacy.[106] Uncontrolled studies have reported less impressive therapeutic responses to cidofovir therapy,[107–109] raising questions about efficacy and safety in laryngeal papillomatosis. Case reports and small case series suggest that cidofovir may be beneficial in the management of adenovirus infections[110–112] and BK virus infections[113,114] in immunocompromised patients.

The recommended induction dose of cidofovir for patients with CMV disease with a serum creatinine level ≤1.5 mg/dL, a calculated CrCl greater than 55 mL/min, and a urine protein level less than 100 mg/dL (i.e., equivalent to <2+ proteinuria) is 5 mg/kg administered once per week for 2 consecutive weeks. The recommended maintenance dose of cidofovir is 5 mg/kg administered once every 2 weeks. The drug should be administered with probenecid, and hydration should be ensured.

Dasabuvir Copackaged With Ombitasvir-Paritaprevir-Ritonavir

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Dasabuvir copackaged with ombitasvir-paritaprevir-ritonavir (Viekira Pak) is an oral regimen composed of four medications: ombitasvir, paritaprevir, ritonavir, and dasabuvir. Ombitasvir, paritaprevir, and ritonavir are combined in a fixed-dose tablet, and dasabuvir is a separate tablet. Dasabuvir is a nonnucleoside inhibitor of the hepatitis C virus (HCV) RNA-dependent RNA polymerase encoded by the gene for nonstructural protein 5B (NS5b), which is essential for replication of the viral genome; its antiviral activity is limited to HCV genotype 1. Ombitasvir is a NS5a inhibitor with potent antiviral activity against HCV genotypes 1 through 6; NS5a is essential for viral RNA replication and virion assembly.

Paritaprevir is an inhibitor of the NS3/4a serine protease of HCV, which is necessary for the proteolytic cleavage of the HCV encoded polyprotein and is essential for viral replication. Paritaprevir has activity against HCV genotypes 1 through 4.

Ritonavir is a potent inhibitor of CYP3A4 enzymes and is used as a pharmacologic booster for paritaprevir. Ritonavir does not have intrinsic activity against HCV. Among patients with on-treatment virologic failure and posttreatment relapse, treatment-emergent mutations were observed in all the three major drug targets (i.e., NS3, NS5a, and NS5b). The efficacy of the Viekira Pak is not known for patients with prior virologic failure and resistance with treatment that included another NS3/4a inhibitor, NS5a inhibitor, or NS5b inhibitor. For patients who develop virologic failure and resistance when treated with the Viekira Pak, the impact on subsequent therapy with other NS3/4a, NS5a, or NS5b inhibitors is unknown.

Pharmacokinetics.

Dasabuvir, ombitasvir, paritaprevir, and ritonavir are absorbed after oral administration, and the mean time to maximal concentration (Tmax) of approximately 4 to 5 hours. Steady-state exposures are achieved after approximately 12 days of dosing. The estimated bioavailability of dasabuvir is approximately 70%, but bioavailability is not known for ombitasvir, paritaprevir, and ritonavir. The median steady-state AUC_{0-24} values for ombitasvir, paritaprevir, and ritonavir are 1000, 2220, and 6180 ng•hr/mL, respectively, and the median steady-state AUC_{0-12} for dasabuvir is 3240 ng•hr/mL. The median steady-state C_{max} values for ombitasvir, paritaprevir, ritonavir, and dasabuvir are 68, 262, 682, and 667 ng/mL, respectively.

Dasabuvir, ombitasvir, paritaprevir, and ritonavir should be administered with a meal. Compared with fasting conditions, administration with a high-fat meal increases the mean AUC by 76%, 180%, 44%, and 22%, respectively. All four components of the Viekira Pak are highly bound (>97%) to human plasma proteins. Dasabuvir is metabolized predominantly by CYP2C8 and to a lesser extent by CYP3A. Ombitasvir is metabolized predominantly by amide hydrolysis followed by oxidative metabolism. Paritaprevir is metabolized predominantly by CYP3A4 and to a lesser extent by CYP3A5. Ritonavir is metabolized predominantly by CYP3A and to a lesser extent by CYP2D6. All four drugs are excreted primarily in the feces.

Toxicity and Drug Interactions.

The Viekira Pak is well tolerated. The most common adverse effects are fatigue, nausea, pruritus, other skin reactions, insomnia, and asthenia. The Viekira Pak has numerous medication contraindications, primarily because of the potent ritonavir inhibition of the CYP3A4 enzyme. Medication contraindications and warnings are listed in the package insert.

Clinical Uses and Recommended Dosage.

Clinical trials assessed efficacy in HCV genotype 1 patients with compensated liver disease with or without cirrhosis for treatment durations of 12 or 24 weeks.[115–119] Sustained virologic responses at

12 weeks (i.e., SVR12) were greater than 96% in all studies involving patients without cirrhosis when the treatment duration was 12 weeks, and sustained virologic responses were greater than 95% for patients with cirrhosis when the treatment duration was 24 weeks (i.e., SVR24). Based on these data, Viekira Pak administered with ribavirin is indicated for use in genotype 1a–infected patients with or without cirrhosis for durations of 24 weeks or 12 weeks, respectively, and for genotype 1b–infected patients with cirrhosis for the treatment duration of 12 weeks. Viekira Pak treatment without ribavirin is indicated in genotype 1b–infected patients without cirrhosis for the treatment duration of 12 weeks. The daily dosage is two ombitasvir, paritaprevir, plus ritonavir 12.5/75/50-mg tablets once daily (in the morning) and one dasabuvir 250-mg tablet twice daily (morning and evening) with a meal without regard to fat or calorie content.

Treatment of HCV with the Viekira Pak has not been studied in children.

Entecavir

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Entecavir (Baraclude) is a guanosine nucleoside analogue, which, after phosphorylation to the active triphosphate form, exhibits potent activity against HBV polymerase.[120–122] Entecavir triphosphate inhibits HBV polymerase base priming, reverse transcription of the negative strand from the pregenomic messenger RNA, and synthesis of positive-strand HBV DNA. It is approximately 30-fold more potent than lamivudine in vitro.[120] Entecavir triphosphate is a weak inhibitor of cellular DNA polymerases, and it does not demonstrate activity against HIV-1 replication.[123,124]

Both in vitro and in vivo data suggest that emergence of resistance to entecavir is rare in nucleoside-naïve patients.[125–130] However, approximately 7% of lamivudine-refractory patients with HBV infection develop entecavir resistance-associated amino acid substitutions at rtI169, rtT184, rtS202, and rtM250 when preexisting lamivudine resistance mutations reL180M or rtM204V/I are present.[131] Additional mutations within the HBV viral polymerase are required for entecavir resistance to develop.[126,127,129] Five-year entecavir-resistance rates are 1.2% for nucleoside-naïve and 51% for lamivudine-refractory patients[125,132] Entecavir is active against adefovir-resistant mutants,[120] and because additional mutations are required to develop resistance to entecavir, the drug also remains active against lamivudine-resistant mutants.[125,133] Emergence of entecavir resistance mutations usually is associated with virologic rebound during therapy.[127]

Pharmacokinetics.

Entecavir peak plasma concentrations occur between 0.5 and 1.5 hours after oral administration in adults. Steady state is achieved after 6 to 10 days of once-daily administration, with approximately twofold accumulation. At steady state, C_{max} is 4.2 ng/mL, and C_{trough} is 0.3 ng/mL. Due to decreases of approximately 20% in the AUC when the drug is administered with food, entecavir should be given at least 2 hours before or after a meal. The intracellular half-life of entecavir triphosphate is 15 hours. Approximately two thirds to three fourths of drug is excreted unchanged in the urine.

Pharmacokinetic studies of entecavir have not been conducted for children younger than 16 years of age.

Toxicity and Drug Interactions.

Coadministration of entecavir in vitro with several HIV nucleoside reverse transcriptase inhibitors (NRTIs) does not impact entecavir anti-HBV activity, and entecavir does not have a detrimental effect on NRTI anti-HIV activity. Entecavir is not a substrate, inhibitor, or inducer of the cytochrome P450 enzyme system, which limits drug interactions. The steady-state pharmacokinetics is not altered when it is coadministered with lamivudine, adefovir dipivoxil, and tenofovir disoproxil fumarate.

As with other therapies for chronic HBV infections, severe acute exacerbations of hepatitis B have been reported in patients who have discontinued entecavir therapy. Hepatic function should be monitored closely with clinical and laboratory follow-up examinations for at least several months for patients who discontinue HBV therapy.

Clinical Uses and Recommended Dosage.

Entecavir is indicated for the treatment of chronic HBV infection in adults with evidence of active viral replication with persistent elevations in serum aminotransferases or histologically active liver disease. Entecavir is superior to lamivudine in the treatment of chronic HBV infection,[134] and it is the most potent anti-HBV agent available.[135,136] When entecavir (0.5 mg once daily) was compared with lamivudine (100 mg once daily) for 52 weeks in nucleoside-naïve patients with compensated liver disease, more of those receiving entecavir had improvement in histologic Knodell necroinflammatory scores in the HBeAg-positive (72% vs. 62%, $P < 0.05$) and HBeAg-negative (70% vs. 61%, $P < 0.05$) subgroups. Similarly, more patients developed normal serum ALT concentrations during therapy with entecavir compared with lamivudine (68% vs. 60% for HBeAg-positive patients, $P < 0.05$; 78% vs. 71% for HBeAg-negative patients, $P < 0.05$). More patients cleared viremia on entecavir compared with lamivudine (67% vs. 36% for HBeAg-positive patients, $P < 0.05$; 90% vs. 72% for HBeAg-negative patients, $P < 0.05$).[137–139] Responses endured through the second year of therapy.[140]

Among patients with lamivudine-refractory chronic HBV infection, changing to entecavir (1 mg once daily) was superior to continuing lamivudine (100 mg once daily).[141] More patients receiving entecavir had improvement in histologic Knodell necroinflammatory scores (55% vs. 28%, $P < 0.01$), in the Ishak fibrosis score (34% vs. 16%, $P < 0.01$), normalization of ALT concentration (61% vs. 15%, $P < 0.0001$), and clearance of viremia (19% vs. 1%, $P < 0.0001$).[132,137]

Entecavir is superior to adefovir dipivoxil in nucleoside-naïve, HBeAg-positive patients.[142] At 12 weeks, the mean change in serum HBV DNA concentration was $-6.23 \log_{10}$ copies/mL in the entecavir group, compared with −4.42 log10 copies/mL in the adefovir dipivoxil group. After 96 weeks of treatment, 97% of entecavir-treated patients had achieved ALT normalization, compared with 85% of adefovir-treated patients (95% confidence interval [CI], 5.4–28.6).[142]

The recommended dose of entecavir for chronic HBV infection in nucleoside-naïve adults and adolescents 16 years of age or older is 0.5 mg once daily. The entecavir dose should be increased to 1 mg once daily in HBV-infected those 16 years of age or older who have a history of HBV viremia while receiving lamivudine or who have a known lamivudine-resistance mutation. The optimal duration of therapy with entecavir is unknown but is being evaluated.[85]

Hemodialysis removes approximately 13% of the entecavir dose over 4 hours, whereas CAPD removes approximately 0.3% of the dose over 7 days. In patients with renal impairment, clearance of entecavir decreases with the rate of CrCl. Dosage adjustment is recommended for patients with a CrCl less than 50 mL/min, including patients on hemodialysis or CAPD. Dosage is 0.25 mg once daily for CrCl values of 30 to less than 50 mL/min, 0.15 mg once daily for CrCl values of 10 to less than 30 mL/min, and 0.05 mg once daily for CrCl values of less than 10 mL/min or CAPD. A supplemental dose should be administered after hemodialysis. These doses are doubled for patients refractory to lamivudine.

Famciclovir and Topical Penciclovir

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Famciclovir (Famvir) is the inactive diacetyl ester prodrug of penciclovir (Denavir), an acyclic nucleoside analogue with a spectrum of activity against herpesviruses similar to that of acyclovir. Its activation by viral and host cell enzymes and its mechanism of action also are akin to those of acyclovir, except that penciclovir is neither an obligate DNA chain terminator nor an inactivator of DNA polymerase. However, laboratory studies suggest that penciclovir triphosphate retards the rate of subsequent nucleotide incorporation.

Penciclovir is approximately 100-fold less potent than acyclovir in inhibiting herpesvirus DNA polymerase activity. However, it remains an effective antiviral agent because of high intracellular concentrations and long half-life. Because penciclovir must be activated by the virus-encoded TK enzyme, TK-deficient viral strains are resistant to acyclovir and penciclovir. Penciclovir persists in high intracellular concentrations much longer than acyclovir. The antiviral effect is more sustained, and the drug can be administered less frequently than acyclovir.

Pharmacokinetics.

After oral administration of famciclovir, the bioavailability of penciclovir is about 70%. Food delays absorption but does not affect the peak plasma drug concentration. Peak concentrations of drug after intravenous administration of 10 mg/kg are approximately sixfold higher than those attained after oral doses of 250 mg. Drug half-life is 2.5 hours. Almost 75% of administered drug is recovered unchanged in the urine, and dose reduction is recommended for those with compromised renal function. A 12-hour dosing interval is recommended for those with CrCl values between 30 and 50 mL/min/1.73 m^2, and a 24-hour interval is recommended for those with CrCl values less than 30 mL/min/1.73 m^2.[143] Measurable penciclovir concentrations are not detectable in plasma or urine after topical administration of penciclovir cream.

Famciclovir pharmacokinetics have been assessed in a single-dose pediatric study of infants 1 to 12 months of age given famciclovir sprinkles orally.[144] Infants younger than 6 months of age had substantially lower systemic exposure compared with those 6 to 12–months of age. A small safety and pharmacokinetic study assessed a single, large dose of famciclovir in adolescents with recurrent herpes labialis.[145]

Toxicity and Drug Interactions.

Famciclovir is as well tolerated as acyclovir. Complaints of nausea, diarrhea, and headache occurred in clinical trials, although at frequencies similar to those reported by placebo recipients.[146] No clinically significant drug interactions have been reported, but concentrations of famciclovir among volunteers increase by about 20% in the patients receiving concomitant cimetidine or theophylline administration.[147]

Clinical Uses and Recommended Dosage.

The efficacy for treatment of uncomplicated herpes zoster was studied in a placebo-controlled, double-blind trial enrolling 419 immunocompetent adults.[148] Treatment was begun within 72 hours of the appearance of lesions, and therapy was continued for 7 days. Famciclovir therapy decreased the median time to full crusting by 2 days. The effects of famciclovir were greater when therapy was initiated within 48 hours of the onset of rash, and effects were more pronounced in patients 50 years of age or older. There were no overall differences in the duration of pain before healing of the rash between the famciclovir-treated and placebo groups. There also was no difference in the incidence of postherpetic neuralgia. Among patients who developed postherpetic neuralgia, however, the median duration of symptoms was shorter for patients treated with famciclovir than those given placebo (63 and 119 days, respectively).

A double-blind, controlled trial enrolling 545 immunocompetent adults with uncomplicated herpes zoster treated within 72 hours of the appearance of lesions compared three doses of famciclovir with acyclovir at a dose of 800 mg given five times per day. The times to full lesion crusting and times to loss of acute pain were comparable for all groups, and there was no statistically significant difference in the time to resolution of postherpetic neuralgia.

Placebo-controlled studies of famciclovir for the episodic treatment of genital HSV[149] and for suppression of genital HSV recurrences[150,151] have shown efficacy and good drug tolerability.[39] Famciclovir was approved by the FDA for the treatment of herpes zoster in 1994 and subsequently was approved for the treatment and suppression of genital HSV disease.

The indications for and recommended dosages of famciclovir are presented in Table 295.9. Dosing in infants and young children has been studied.[144] Dosing recommendations for children 6 months to 12 years of age are based on pharmacokinetic modeling and have not been studied adequately to warrant dosing recommendations in this age group.

TABLE 295.9

Famciclovir: Indications and Dosages

Infection	Dosage	Duration
Zoster	500 mg tid	7 days
Recurrent genital HSV, immunocompetent host (episodic therapy)	1000 mg bid	1 day
Recurrent genital HSV, immunocompetent host (suppressive therapy)	250 mg bid	Up to 1 year
Recurrent genital HSV, immunocompromised host (episodic therapy in compromised hosts)	500 mg bid	7 days
Recurrent orolabial HSV, immunocompromised host (episodic therapy)	500 mg bid	7 days
Recurrent orolabial HSV, immunocompetent host (episodic	1500 mg	Administer as a

therapy)		single dose

HSV, herpes simplex virus.

Topical penciclovir for the treatment of recurrent herpes labialis reduces the time to healing and the duration of pain by about one half of a day.[152,153] Application of medicine should begin as early as possible, preferably during the prodromal phase, and should be continued every 2 hours during waking hours for 4 days.

Ganciclovir and Valganciclovir

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Ganciclovir (Cytovene) is a nucleoside analogue that is different from acyclovir by having an extra hydroxymethyl group on the acyclic side chain.[154] Its greatest in vitro activity is against CMV (see Table 295.4), although it is also as active as acyclovir against HSV-1 and HSV-2 and almost as active against VZV.

As with acyclovir and penciclovir, the first step in ganciclovir phosphorylation is carried out by a virus-encoded enzyme, and the final steps are achieved by cellular enzymes. CMV lacks the gene for TK, and the enzyme that catalyzes the initial phosphorylation of ganciclovir in CMV-infected cells is the phosphotransferase encoded by the *ul97* gene.[155,156] Intracellular ganciclovir triphosphate concentrations are at least 10-fold higher in CMV-infected cells than in noninfected cells,[157] and intracellular ganciclovir triphosphate has a half-life of 24 hours or longer.

Ganciclovir triphosphate is a competitive inhibitor of herpesvirus DNA polymerases, although it has some activity against cellular DNA polymerases. This potential for incorporation into host cellular DNA accounts for ganciclovir's substantial toxicity. Incorporation of ganciclovir triphosphate into the growing viral DNA chain results in slowing and subsequent cessation of DNA chain elongation.[158]

Valganciclovir (Valcyte) was approved by the FDA in 2001. Because valganciclovir is well absorbed after oral administration, it can be a favorable alternative to intravenously administered ganciclovir for the treatment and suppression of CMV infections in immunocompromised hosts. Valganciclovir is an L-valine ester prodrug of ganciclovir and has the same mechanism of action and antiviral spectrum as ganciclovir.[159]

Ganciclovir resistance among CMV isolates is conferred by mutations in the *UL97* gene or the CMV DNA polymerase gene. Of these two mechanisms of antiviral resistance, ganciclovir-resistant CMV isolates with mutations in the *UL97* open reading frame are the predominant phenotype.[93] Specific mutations in the *UL97* region can be detected rapidly in plasma and serum by direct sequencing of polymerase chain reaction (PCR)–amplified CMV DNA.[160]

Resistant strains of CMV should be suspected when progressive disease and continued recovery of virus occur despite ganciclovir therapy. In one study, 8% of 72 patients with AIDS had progressive infection associated with isolation of ganciclovir-resistant strains of CMV after 3 months of continuous ganciclovir therapy.[161] Resistance may be more likely in patients treated with oral ganciclovir than in those treated with intravenous ganciclovir because of the selective pressure applied by the lower concentrations of drug achieved with oral administration.[162] In contrast, CMV isolates from solid-organ transplant recipients who have been exposed to ganciclovir appear less likely to develop resistance.[163] Foscarnet may be useful in the treatment of CMV infections caused by ganciclovir-resistant isolates.[164]

Occasionally, strains of HSV that are resistant to acyclovir because of TK deficiency also are less sensitive to ganciclovir.[165] Ganciclovir-resistant isolates of HSV due to mutations in DNA polymerase have been demonstrated in the laboratory but have not become a clinical problem.

The mechanism of resistance to ganciclovir and valganciclovir are the same.[159] Selective pressure resulting from exposure to lower concentrations of drug appears to increase the likelihood of resistance developing among CMV isolates,[162] and it is thought that the higher serum and tissue concentrations of ganciclovir achieved with administration of valganciclovir produces less emergence of resistance compared with oral ganciclovir. Small studies have indicated that rates of resistance among valganciclovir recipients are similar to those of intravenous ganciclovir recipients[166] and are less than those of patients taking ganciclovir orally.[167]

Pharmacokinetics.

Peak serum concentrations of ganciclovir attained after 5 mg/kg administered intravenously range from 8 to 11 μg/mL.[154] Concentrations sufficient to inhibit susceptible strains of CMV are attained in aqueous humor, subretinal fluid, CSF, and brain tissue. Most of an administered dose of ganciclovir is eliminated unchanged in the urine; the elimination half-life is 2 to 3 hours.[15] Dose reduction, roughly proportional to the degree of reduction in CrCl, is necessary in patients with impaired renal function (see Table 295.6).[160,168] For CrCl values of 50 to less than 80 mL/min/1.73 m^2, one half of the usual dose should be given every 12 hours. The same dose should be given every 24 hours for CrCl values of 25 to less than 50 mL/min/1.73 m^2, and 25% of the usual dose should be given every 24 hours for CrCl values of less than 25 mL/min/1.73 m^2. Because ganciclovir is efficiently removed by hemodialysis, a supplemental dose is recommended after dialysis.[168]

The pharmacokinetics of ganciclovir in the neonatal population are similar to those of adults.[169] After intravenous administration of 6 mg/kg of ganciclovir, peak concentrations of 7 μg/mL are achieved. The mean elimination half-life is 2.4 hours. Pharmacokinetics of oral valganciclovir have been compared with those of parenteral ganciclovir in this population.[170] Intravenous ganciclovir clearance almost doubled, and the AUC_{12} was reduced by almost one half over the first 6 weeks of life. In comparison, only a marginal decrease in AUC_{12} was seen after administration of valganciclovir oral solution, possibly because bioavailability increased by 32% over the same period.

Bioavailability of oral ganciclovir is poor, with less than 10% of the drug absorbed after oral administration.[171] Despite this, an oral dose of 1000 mg of ganciclovir produces a peak plasma concentration of 1 μg/mL, a level that is above the inhibitory concentration for most CMV clinical isolates. Intravitreal drug concentration achieved during intravenous induction therapy averages 1 μg/mL, whereas the subretinal concentration is comparable with that of plasma.[172,173] The concentration of ganciclovir in the CNS is 24% to 70% of the plasma level, and the brain concentration is approximately 38% of plasma level.[174]

Valganciclovir is rapidly converted to ganciclovir, with a mean plasma half-life of about 30 minutes.[175] The absolute bioavailability of valganciclovir exceeds 60%, and it is enhanced by about 30% with concomitant administration of food.[176] Oral valganciclovir produces exposures of ganciclovir exceeding those attained with oral ganciclovir and are similar to those reported after standard intravenous administration of ganciclovir.[177] Patients with impaired renal function require dosage reduction roughly proportional to their reduction in CrCl.[159]

Toxicity and Drug Interactions.

The most important toxic effect of ganciclovir is myelosuppression. Dose-related neutropenia, defined as a more than 50% decrease in absolute neutrophil count from baseline or less than 1000/mm^3, is the most consistent hematologic disturbance.[154] The incidence of neutropenia during a 2-week course is about 40%. It is dose limiting in about 15% of courses, and it is reversible on cessation of the drug.[154] The likelihood of neutropenia occurring after oral administration of ganciclovir is lower, with 14% to 24% of patients developing an absolute neutrophil count of less than 1000/mm^3.[178]

Hematopoietic growth factors may be useful in preventing or counteracting neutropenia.[179] Thrombocytopenia (<50,000 platelets/mm^3) occurs in approximately 20% of treated patients. Anemia occurs in only about 2% of ganciclovir recipients.

Approximately 5% of ganciclovir recipients experience some combination of headache, confusion, altered mental status, hallucinations, nightmares, anxiety, ataxia, tremors, and seizures. About 2% of recipients develop fever, rash, and abnormal levels of serum hepatic enzymes. Intraocular injection of ganciclovir can cause transient increases in intraocular pressure with associated intense pain and amaurosis lasting up to 30 minutes.[180]

In preclinical test systems, ganciclovir is mutagenic, carcinogenic, and teratogenic. It also causes irreversible reproductive toxicity in animals.[181]

The most common side effects associated with valganciclovir therapy include diarrhea (41%), nausea (30%), neutropenia (27%), anemia (26%), and headache (22%).[159] Up to 5 years of treatment with valganciclovir is well tolerated in patients with AIDS, and the type and incidence of adverse events experienced long term appear to be similar to those observed at 1 year.[182]

Clinical Uses and Recommended Dosage.

Ganciclovir is indicated for the treatment and prevention of life- and sight-threatening CMV infections occurring in immunosuppressed patients.[154] It is approved in the United States for the treatment and suppression of retinitis caused by CMV in immunocompromised patients and for the prevention of CMV disease in transplant recipients. It is frequently used for other serious CMV infections.

Almost 90% of patients with CMV retinitis have improvement or stabilization of the ocular disease and clearing of the condition, demonstrated by a more than 100-fold reduction in viral titers, from urine, blood, the and throat after 1 to 2 weeks of ganciclovir therapy.[179] Because relapse of retinitis is virtually inevitable in patients with AIDS, ganciclovir should be continued long term for CMV suppression after induction therapy.

Patients in whom ganciclovir therapy has failed may benefit from treatment with a combination of foscarnet and ganciclovir.[183] Patients with AIDS who have CNS disease caused by CMV also have been treated successfully with a combination of ganciclovir and foscarnet.[184] As many as 25% of ganciclovir recipients develop resistance within 9 months of the initiation of therapy.[185,186]

Patients with AIDS and solid-organ transplant recipients who have gastrointestinal disease attributed to CMV appear to benefit from ganciclovir therapy.[187,188] Ganciclovir monotherapy does not appear to benefit bone marrow recipients with CMV gastrointestinal infections.[189]

Limited and uncontrolled data suggest that ganciclovir therapy may be useful in patients with AIDS and CMV pneumonia.[154] Bone marrow transplant recipients with CMV pneumonia fail to respond to ganciclovir therapy alone[190] but may benefit from therapy with intravenous CMV hyperimmunoglobulin and ganciclovir given together.[191,192]

Ganciclovir has been evaluated in the treatment of neonates congenitally infected with CMV. In a phase III randomized, controlled trial, ganciclovir therapy (6 mg/kg per dose administered every 12 hours intravenously for 6 weeks) protected infants from hearing deterioration beyond 1 year of life,[193] and it may improve neurologic outcomes.[194] Transient positive effects on growth also were seen, as was a decreased time to resolution of elevated serum hepatic transaminase levels. Approximately two thirds of treated patients, however, developed neutropenia, and one half required dose modification.

A phase I/II pharmacokinetic and pharmacodynamic study of oral valganciclovir established that a 16-mg/kg dose of oral valganciclovir produced similar systemic exposure to that of a 6-mg/kg dose of intravenous ganciclovir.[170] This dose of valganciclovir was then evaluated in a randomized, double-blind, controlled trial enrolling infants with symptomatic congenital CMV disease.[195] Durations of therapy for 6 weeks and 6 months were compared. The longer duration of therapy improved audiologic and neurodevelopmental outcomes more than that seen with 6 weeks of treatment. Neutropenia was less prevalent than with parenterally administered ganciclovir.

Ganciclovir is useful for the prevention of CMV infections in high-risk immunocompromised patients, including bone marrow and solid-organ transplant recipients (see Table 295.8). Strategies that have been used to reduce the frequency of posttransplantation disease include routine administration of ganciclovir to all recipients at risk and pre-emptive administration to those who have a positive culture for CMV after transplantation. Pre-emptive therapy has been demonstrated to reduce CMV disease in recipients of liver,[196] lung,[197] heart,[198] and bone marrow transplants.[199–201] CMV-seropositive recipients of heart, lung, or liver transplants who receive routine prophylaxis with ganciclovir for 1 month also have significant reductions in posttransplant CMV infection and disease.[35,202–205] Pre-emptive administration of ganciclovir improves survival of bone marrow transplant recipients,[206,207] whereas routine initiation of prophylactic ganciclovir before bone marrow transplantation in patients who are CMV seropositive does not impact survival.[207,208] Ultimately, however, the best strategy has not been determined for preventing primary CMV infections in CMV-seronegative solid-organ transplant recipients who receive an organ from a CMV-seropositive donor.

The usual therapeutic and prophylactic dose of intravenous ganciclovir is 10 mg/kg/day divided every 12 hours for 2 to 3 weeks. For continued suppressive therapy to prevent relapse of infection (e.g., patients with AIDS) or long-term prophylaxis, either of the following may be used: 5 mg/kg as a single daily dose each day of the week or 6 mg/kg administered as a single dose 5 days per week. Prophylactic oral ganciclovir (1000 mg three times daily) significantly reduces the risk of CMV disease in patients with advanced AIDS.[209]

Indications for valganciclovir are similar to those for ganciclovir. However, based on limited controlled trials, valganciclovir is approved only for induction and maintenance therapy for CMV retinitis.[210] The recommended dose of valganciclovir for induction therapy is 900 mg twice daily for 2 weeks. The recommended dose for maintenance therapy is 900 mg once daily. Orally administered valganciclovir appears to be as effective as intravenous ganciclovir for induction treatment and is convenient and effective for the long-term management of CMV retinitis in patients with AIDS.

The greater systemic exposure to ganciclovir delivered by valganciclovir when used prophylactically is safe and is associated with delayed development of viremia compared with oral ganciclovir in solid-organ transplant recipients.[211–213] Valganciclovir also is effective as pre-emptive therapy[214–216] and as treatment for CMV disease[217] in solid-organ transplant recipients.

Lamivudine

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Lamivudine (Epivir) is a nucleoside analogue that is phosphorylated to lamivudine triphosphate by cellular kinases. Lamivudine inhibits the reverse transcriptase of HBV and HIV, and it is indicated for the treatment of HIV and chronic HBV infection.

Lamivudine-resistant HBV mutants occur in up to one third of patients by the end of 1 year of therapy and in up to two thirds of them by the end of 4 years of drug exposure.[218] The most common mutation affects the tyrosine-methionine-aspartate-aspartate (YMDD) motif in the catalytic domain of the HBV polymerase, resulting in a change from methionine to valine (M522V) or isoleucine (M522I).

Pharmacokinetics.

Lamivudine at a dose of 4 mg/kg administered twice daily produces an AUC_{12} of 5.16 mg•hr/L and half-life ($t_{1/2}$) of 1.76 hours. The half-life in children is less than the half-life in adults (i.e., 3.5 hours).[219]

Toxicity and Drug Interactions.

Adverse reactions to lamivudine include pancreatitis, paresthesia, peripheral neuropathy, neutropenia, anemia, rashes, nausea, vomiting, and hair loss.

Clinical Uses and Recommended Dosage.

In the treatment of chronic HBV infection, lamivudine decreases serum HBV DNA by 3 to 4 log copies per mL in most patients. Among patients who are HBeAg positive, approximately 20% achieve HBeAg seroconversion and undetectable serum HBV DNA at the end of 1 year of lamivudine therapy.[218,220,221] Approximately one half of treated patients experience improvement in histologic liver abnormalities. Similar findings have been seen in children.[222]

Lamivudine resistance usually manifests as breakthrough infection defined as reappearance of HBV DNA in serum after its initial disappearance.[223] This occurs in approximately two thirds of patients within 3 years of starting therapy.[224] Most patients continue to have lower serum HBV DNA and ALT levels compared with pretreatment values, perhaps due to decreased fitness of the lamivudine-resistant mutants. On cessation of lamivudine therapy, most patients experience an increase in serum HBV DNA concentrations.[225]

Lamivudine is indicated for the treatment of HIV and chronic HBV infection. Epivir tablets and oral solution for HBV infection contain a lower dose of lamivudine than Epivir tablets and oral solution used for HIV infection. The formulation and dosage of lamivudine in Epivir for HBV are not appropriate for patients dually infected with HIV and HBV; rapid emergence of HIV resistance is likely to result because of the subtherapeutic dose for HIV. The recommended oral dose of lamivudine for HBV-infected adults is 100 mg once daily. For HBV-infected children 2 through 17 years of age, the dose is 3 mg/kg (maximal dose: 100 mg) administered once daily.

Ribavirin

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Ribavirin (Virazole, Rebetron combination therapy) is a synthetic nucleoside analogue developed in 1972 that most closely resembles guanosine in structure.[226] Ribavirin is absorbed rapidly across cell membranes and is enzymatically converted by host cell enzymes into its 5′-phosphate derivatives and the deribosylated base.[227] These metabolites interfere with the capping and elongation of messenger RNA. Ribavirin also appears to reduce guanine nucleosides by feedback inhibition.[228]

Although more potent against RNA viruses, ribavirin is active in vitro against a wide range of RNA and DNA viruses, including myxoviruses, paramyxoviruses, arenaviruses, bunyaviruses, herpesviruses, adenoviruses, poxviruses, and retroviruses.[229,230] It is approved in the United States for the treatment of RSV infections and, in combination with interferon, for hepatitis C virus infections. Resistance to ribavirin has not been observed, although Sindbis virus mutants with diminished susceptibility to ribavirin have been reported.[231]

Pharmacokinetics.

Ribavirin can be administered orally, intravenously, or by aerosol. Only the aerosolized formulation of drug (Virazole) and the oral formulation (in combination in interferon α [Rebetol]) or peginterferon α-2a [Copegus]) are approved for use in the United States.

About 40% of orally administered ribavirin is absorbed; after doses ranging from 600 to 2400 mg, peak plasma concentrations range from 1.3 to 3.2 μg/mL.[232] Peak concentrations after intravenous therapy are approximately 10-fold greater. Ribavirin and its metabolites concentrate in red blood cells. The levels in CSF are approximately 70% of the plasma concentration of the drug.[233] About one fourth to one third of systemically administered ribavirin is recovered unchanged in urine, and an additional 6% to 30% is excreted as metabolites. The terminal half-life of ribavirin is 18 to 36 hours, but some drug persists in red blood cells for several weeks after administration.[232]

Toxicity and Drug Interactions.

Ribavirin administered by the oral and intravenous routes causes dose-related, reversible anemia.[232] At low doses of the drug, anemia results from extravascular hemolysis, whereas at high doses, anemia is caused by bone marrow suppression. Increases in serum bilirubin, iron, and uric acid also occur with systemic ribavirin therapy.

Clinical Uses and Recommended Dosage.

Systemic ribavirin has demonstrated efficacy in the management of life-threatening infections caused by Lassa fever and hemorrhagic fever with renal syndrome.[234,235] Orally and intravenously administered ribavirin substantially reduce the mortality and morbidity directly attributable to each of these infections, and oral ribavirin has been recommended for prophylaxis against Lassa fever in exposed people.[236] Clinical benefit also has been observed in the treatment of Argentine and Bolivian hemorrhagic fever[237] and laboratory-acquired Sabia virus infection.[238]

Simeprevir

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Simeprevir (Olysio, Galexos) is an inhibitor of the NS3/4A serine protease of HCV, which is necessary for the proteolytic cleavage of the HCV-encoded polyprotein and is essential for viral replication. Simeprevir has demonstrable in vitro activity against HCV genotypes 1a, 1b, and 4 using different cell-based replicon assays.

Several amino acid substitutions at NS3 protease positions confer reducted activity, including F43, Q80, S122, R155, A156, and D168. The baseline prevalence of Q80K is 30% in genotype 1a–infected patients, but is less than 1% in genotype 1b–infected patients. The Q80K polymorphism is associated with a lower sustained virologic response in clinical trials. Baseline determination of the Q80K polymorphism should be obtained before initiation of treatment with simeprevir.

Pharmacokinetics.

Simeprevir has good oral bioavailability. The drug is highly bound to human plasma proteins. Time to maximal concentration (T_{max}) is 4 to 6 hours, and the half-life is 10 to 13 hours. Steady state is reached after 7 days of once-daily dosing. High plasma concentrations are achieved, with a mean AUC_{24} of 57,469 ng•hr/mL. Simeprevir is metabolized primarily by CYP3A, and it is eliminated predominantly in the feces by biliary excretion.

Toxicity and Drug Interactions.

The most common adverse effects are rash (including a potentially serious photosensitivity reaction), pruritus, and nausea. The photosensitivity reaction usually starts within the first 4 weeks of therapy, but it can develop at any time during treatment. Patients taking simeprevir should limit sun exposure, use protective sunscreen when exposure is unavoidable, and avoid use of all tanning devices. If a photosensitivity rash occurs, discontinuation of drug should be considered, and the patient should have close monitoring until the rash has resolved. Patients also can experience transient increase in serum bilirubin level that peaks at week 2 of treatment and typically is mild.

Due to its metabolism by CYP3A enzymes, administering simeprevir with medications that have moderate or strong induction of CYP3A, such as rifampin, St. John's wort, and most anticonvulsants, can significantly reduce levels of simeprevir. In contrast, medications that have moderate or strong inhibition of CYP3A, such as clarithromycin, ketoconazole, and ritonavir, can significantly increase levels of simeprevir. Simeprevir also has complex drug-drug interactions with many antiretroviral medications. Medication contraindications and warnings are listed in the package insert.

Clinical Uses and Recommended Dosage.

Simeprevir has been evaluated in treatment-naïve, genotype 1–infected HCV patients,[239,240] genotype 1–infected patients who have relapsed after prior interferon-based therapy,[241] and genotype 1–infected patients who failed prior peginterferon and ribavirin therapy.[242] In treatment-naïve patients, the combination of simeprevir, peginterferon, and ribavirin for 12 weeks followed by 12 or 36 weeks of therapy with interferon and ribavirin produced SVR12 for approximately 80%. Comparable results were seen in patients who relapsed after prior therapy, but only one half of prior null responders had a sustained virologic response to simeprevir therapy in combination with peginterferon and ribavirin. In combination with sofosbuvir in prior null responders to peginterferon and ribavirin, simeprevir plus sofosbuvir produced sustained virologic response rates of 93% (SVR12) to 97% (SVR24).[243]

Simeprevir is indicated for the treatment of chronic HCV genotype 1 infection as a component of a combination antiviral treatment regimen. Simeprevir monotherapy is not recommended. When used in combination with peginterferon and ribavirin, screening patients with genotype 1a infection for the presence of the NS3 Q80K polymorphism is strongly recommended. The dosage of simeprevir used in all combination regimens is 150 mg administered once daily. The recommended duration of treatment when administered with peginterferon and ribavirin is 12 weeks followed by 12 or 36 additional weeks of peginterferon and ribavirin, depending on prior response status. When administered in combination with sofosbuvir, treatment duration is 12 weeks in treatment-naïve or treatment-experienced patients without cirrhosis and 24 weeks in treatment- naïve or treatment-experienced patients with cirrhosis.

Simeprevir has not been studied in children.

Sofosbuvir and Sofosbuvir-Ledipasvir

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Sofosbuvir (Sovaldi) is a nucleotide analogue inhibitor of HCV NS5B polymerase, which is the key enzyme mediating HCV RNA replication. Sofosbuvir is efficiently taken up by hepatocytes and then undergoes triphosphorylation to its active form. Sofosbuvir triphosphate then competes with uridine to be incorporated by the HCV RNA polymerase into the elongating RNA primer strand, resulting in chain termination.

The active site of the NS5B enzyme is relatively well conserved across genotypes, yielding activity of sofosbuvir in HCV genotypes 1 through 6. The S282T amino acid substitution in HSV NS5B polymerase reduces sensitivity to sofosbuvir in cell culture. This mutation has not been detected in untreated patients, and it is rare in sofosbuvir-treated patients. The M289L substitution in genotype 2, 5, and 6 replicons also is associated with reduced activity of sofosbuvir. In phase III clinical trials, treatment-emergent substitutions L159F and V321A were detected in postbaseline samples from genotype 3–infected subjects with virologic failure. Cross-resistance between sofosbuvir, ledipasvir, and ribavirin has not been identified.

Ledipasvir is a potent inhibitor of HCV nonstructural protein 5A (NS5A), a viral phosphoprotein that plays an important but poorly understood role in viral replication, assembly, and secretion.[244] Ledipasvir is approved for the treatment of genotype 1 HCV. Its safety and efficacy have not been fully established for genotypes 2 through 6. NS5A amino acid substitutions Y93H (in genotypes 1a and 1b) and Q30E (in genotype 1a) significantly reduce susceptibility to ledipasvir in cell culture and in clinical studies.[245] Other amino acid substitutions observed in virologic treatment failures are K24R, M28T/V, Q30H/K/L (genotype 1a), and L31V/M/I (genotype 1b). Viruses with these resistance-associated mutations remained susceptible to sofosbuvir.

Pharmacokinetics.

Oral bioavailability of sofosbuvir is at least 80% based on urinary recovery. Ledipasvir also is well absorbed orally. Approximately 65% of sofosbuvir is bound to human plasma protein, and virtually all of ledipasvir is plasma protein bound.

The sofosbuvir T_{max} is 0.5 to 2 hours, with peak plasma concentration of the active metabolite occurring 2 to 4 hours after dosing. The T_{max} for ledipasvir is 4 to 4.5 hours. The terminal half-life for sofosbuvir and its active metabolite are 0.4 and 27 hours, respectively, and the terminal half-life for ledipasvir is 47 hours. Sofosbuvir primarily is eliminated in the urine, whereas ledipasvir elimination occurs primarily through the biliary tract. Eighty percent of sofosbuvir is recovered in the urine, primarily as the active metabolite, and 86% of ledipasvir is recovered in the feces.

Toxicity and Drug Interactions.

Common adverse events with sofosbuvir treatment are fatigue (when used with ribavirin), and anemia, neutropenia, insomnia, headache, and nausea (when used with peg interferon and ribavirin). Increases in bilirubin, creatinine kinase, and lipase levels can occur. Headache and fatigue are common adverse events of ledipasvir, and elevated bilirubin and lipase can occur. Sofosbuvir-ledipasvir (Harvoni) has significant drug-drug interactions with P-glycoprotein inducers (e.g., St. John's wort, rifampin), decreasing the ledipasvir and sofosbuvir plasma concentrations. The concomitant use of sofosbuvir-ledipasvir with P-glycoprotein inducers is not recommended.

Clinical Uses and Recommended Doses.

The combination of ledipasvir and sofosbuvir has primarily been studied as an all-oral combination regimen, without the requirement for interferon, in treatment-naïve and treatment-experienced patients with genotype 1 chronic HCV infection. Three phase III studies have consistently shown the SVR12 rates to be greater than 90% after a 12-week course of ledipasvir-sofosbuvir in patients with genotype 1 chronic HCV infection.[246–248] For treatment-experienced patients with cirrhosis, the SVR12 rates were significantly better with 24 weeks of therapy than with 12 weeks.[246] A subanalysis of one of the trials showed that treatment-naïve patients without cirrhosis had excellent SVR12 rates with only 8 weeks of ledipasvir-sofosbuvir if their pretreatment HCV RNA level was less than 6 million IU/mL.[248] For the treatment of patients with genotype 1 infection, the addition of ribavirin to ledipasvir-sofosbuvir did not provide significant benefit.

The approved clinical use for ledipasvir-sofosbuvir is only for chronic genotype 1 HCV-infected adults. The recommended treatment duration is 12 weeks for treatment-naïve adults with or without cirrhosis (with the caveat that 8 weeks of treatment can be considered in treatment- naïve patients without cirrhosis who have a pretreatment HCV RNA level less than 6 million IU/mL), 12 weeks for treatment-experienced adults without cirrhosis, and 24 weeks for treatment-experienced adults with cirrhosis. The recommended dose is 400 mg of sofosbuvir and 90 mg of ledipasvir, which are combined in a single tablet taken daily.

Sofosbuvir is administered in combination with peginterferon and ribavirin (in treatment-naïve subjects with genotype 1, 4, 5, or 6)[249] or in combination with ribavirin only in treatment-naïve subjects with genotype 2 or 3; interferon intolerant, ineligible, or unwilling subjects; patients previously treated with an interferon-based regimen; and subjects irrespective of prior treatment history or ability to take interferon.[249–251] High sustained virologic response rates were seen in these studies, resulting in the FDA indications for sofosbuvir in combination with peginterferon and ribavirin for patients with genotypes 1 or 4 (i.e., 12-week treatment duration), in combination with ribavirin for patients with genotype 2 (i.e., 12-week treatment duration), and in combination with ribavirin for patients with genotype 3 (i.e., 24-week treatment duration). With each of these treatment combinations, the dose of sofosbuvir is 400 mg once daily.

Neither sofosbuvir nor ledipasvir has been studied in children.

Telbivudine

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Telbivudine (Tyzeka) is the unmodified L-enantiomer of the naturally occurring nucleoside D-thymidine.[252,253] Host cell kinases phophorylate telbivudine to telbivudine-5′-triphosphate, which then is incorporated into HBV DNA, resulting in viral DNA chain termination.[253,254] Telbivudine preferentially inhibits HBV second-strand (DNA-dependent) DNA synthesis.[255] In comparison, lamivudine preferentially inhibits first-strand (RNA-dependent) DNA synthesis.[255] Telbivudine is active only against hepadnaviruses.[253,254] Coadministration of telbivudine with lamivudine does not produce additive or synergistic effects.[256]

In vitro, telbivudine-5′-triphosphate has no inhibitory effect on host cell DNA polymerases α, β, or γ at concentrations up to 100 μmol/L.[252,254] In contrast, the mean 50% effective concentration (EC_{50}) inhibiting HBV DNA polymerase is 0.12 to 0.24 μmol/L,[254] illustrating the specificity and potency of the drug for HBV replication. At concentrations up to 10 μmol/L, telbivudine has minimal toxic effect on host cell mitochondria and does not increase lactic acid production.[252,254]

The key determinant of telbivudine resistance is the M204I mutation in the YMDD motif.[254] The principal mutations conferring in vivo lamivudine resistance do not produce cross-resistance to telbivudine,[257] but cross-resistance can be induced in vitro.[258] Telbivudine is active or has slightly reduced activity in vitro against adefovir-resistant HBV strains.[257]

Pharmacokinetics.

Telbivudine is absorbed rapidly after oral administration, and it is not influenced by food.[259] The half-life is about 40 hours. Approximately 40% of the dose is excreted as the unchanged active substance by the kidneys, likely by renal filtration.[254] Systemic exposure to telbivudine is increased in patients with impaired renal function, and in patients with moderate to severe renal impairment (CrCl <50 mL/min) or end-stage renal disease requiring dialysis, the dosing interval requires adjustment.[260]

Dosage adjustment is not required for patients with impaired hepatic function. Dosages of 20 mg/kg/day for children and 600 mg/day for adolescents produce exposures similar to those in healthy adults receiving 600 mg/day.[261]

Toxicity and Drug Interactions.

No dose-related or dose-limiting toxicity has been identified in healthy volunteers or patients with chronic hepatitis B infection.[262,263] Elevated serum creatinine kinase (CK) concentration is the most frequent adverse event. Cases of myopathy during therapy have been described, but they did not correlate with the magnitude or timing of CK elevations.[254,264] Nevertheless, treatment should be discontinued if persistent, unexplained muscle-related symptoms occur.[254,264] Patients receiving telbivudine along with other drugs associated with myopathy, such as cyclosporin or HMG-CoA reductase inhibitors (i.e., statins) should be monitored closely for signs and symptoms of myopathy.[254]

There are no clinically significant interactions between telbivudine and adefovir, tenofovir, and lamivudine.[265] The drug does not induce or inhibit cytochrome P450. Coadministration of telbivudine with drugs that affect renal function (e.g., aminoglycosides, amphotericin B) can impact plasma concentrations of either drug.[254]

Clinical Uses and Recommended Doses.

Telbivudine is licensed for use in adolescents and adults (≥16 years of age). In HBeAg-seropositive and -seronegative adults, telbivudine is superior to lamivudine after 1 and 2 years of therapy.[266,267] The rate of HBeAg seroconversion was 22%, and viral suppression (<300 copies/mL) was achieved in 60% of HBeAg-positive patients after 1 year of therapy.[256] Telbivudine compared with adefovir also has better early viral suppression at week 24 in HBeAg-positive patients, regardless of whether the patients were treated initially with telbivudine or switched from adefovir to telbivudine.[268] The early virologic suppression resulted in better rates of HBeAg seroconversion, serum ALT normalization, and viral suppression.[269] Pediatric efficacy studies are being conducted.[261]

Tenofovir Disoproxil Fumarate

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Tenofovir disoproxil fumarate (Viread) is a nucleoside phosphonate diester analogue of deoxyadenosine 5′-monophosphate and a prodrug of tenofovir.[270,271] After absorption from the gastrointestinal tract, the prodrug is hydrolyzed to tenofovir, which is taken up in target cells and phosphorylated to the active drug tenofovir diphosphate. Tenofovir diphosphate is a competitive inhibitor of the nucleotide deoxyadenosine 5′-triphosphate for incorporation by HBV polymerase into viral DNA, and it inhibits HBV DNA replication by leading to chain termination.[270,272] In addition to HBV, tenofovir diphosphate competitively inhibits deoxyadenosine triphosphate as a substrate for HIV-1 reverse transcriptase, resulting in chain termination after its incorporation in HIV DNA.

Tenofovir diphosphate selectively inhibits viral DNA polymerase, and it produces only weak inhibition of human cellular DNA polymerase α, β, and γ.[272] The active compound is a potent inhibitor of HBV DNA polymerase, with an inhibition constant (K_i) of 0.18 μmol/L.[273] At in vitro concentrations of 300 μmol/L or less, tenofovir diphosphate does not inhibit synthesis of mitochondrial DNA or result in lactic acid production.[270]

Resistance to tenofovir can be generated in HBV in vitro, but antiviral resistance does not appear to be a clinical problem in vivo. In clinical studies, no HBV mutations associated with resistance to tenofovir disoproxil fumarate have been identified, even after 96 weeks of treatment, in immunocompetent and HIV-infected patients.[270,274–278] Cross-resistance between tenofovir and adefovir has been demonstrated from in vivo isolates[273] but not for telbivudine or lamivudine.[279]

Pharmacokinetics.

After oral administration, tenofovir disoproxil fumarate is rapidly absorbed and converted to tenofovir. Oral bioavailability is about 25% in fasting patients or after a light meal, and is about 39% after a high-fat meal.[270,271,280] The half-life of tenofovir is approximately 17 hours.[270] The estimated intracellular half-life of tenofovir diphosphate is 95 hours.[273] Approximately 70% to 80% of the tenofovir dose is excreted unchanged in the urine up to 72 hours after administration.[270,271] In patients with moderate to severe renal impairment (CrCl <50 mL/min), the dosing interval requires adjustment. Dosage adjustment is not required for patients with impaired hepatic function.[270,271]

Toxicity and Drug Interactions.

Tenofovir disoproxil fumarate is usually well tolerated for extended periods.[270,274] Mild adverse reactions to therapy include headache, nasopharyngitis, and gastrointestinal upset. Neither tenofovir disoproxil fumarate nor tenofovir is metabolized by CYP450 enzymes. Although decreased metabolism of CYP1A substrates has been observed,[271] drug interactions mediated by CYP450 enzymes are minimal with tenofovir.

Coadministration of tenofovir disoproxil fumarate with nephrotoxic drugs or compounds that compete for active tubular secretion can result in increased serum concentrations of tenofovir. Tenofovir disoproxil fumarate should not be administered with adefovir dipivoxil.[271] Renal function should be closely monitored if tenofovir disoproxil fumarate is coadministered with tacrolimus.[270] No drug interactions were observed with coadministration with telbivudine,[281] and use with entecavir has not been evaluated.[270,271]

Clinical Uses and Recommended Doses.

Although tenofovir is licensed for use in children at least 12 years of age with HIV infection, it is not approved for use in the treatment of HBV in children. There is no recommended dose for children with HBV infection. In adults, tenofovir is more potent than adefovir in achieving viral suppression (76% vs. 13% with <400 copies/mL), histologic improvement (67% vs. 12%), and higher rates of HBsAg loss (3.2% vs. 0%) at 48 weeks in HBeAg-seropositive patients with chronic HBV infection.[274] Almost 90% of patients maintained serum HBV DNA levels of less than 400 copies/mL when continued on tenofovir disoproxil fumarate for 72 weeks, and almost 80% of patients who did not achieve complete viral suppression did so after 24 weeks of tenofovir therapy.[282] Similar results have been observed in other studies.[281]

The recommended dose for adults is 300 mg taken orally once daily without regard to food. Administration of tenofovir to HBV-infected pregnant women in the latter weeks of pregnancy and the first month postpartum decreases HBV transmission to the neonates.[283]

Inorganic Pyrophosphate Analogues

Foscarnet

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Foscarnet (Foscavir), or phosphonoformic acid (PFA), is an inorganic pyrophosphate analogue that inhibits all known human herpesviruses, including most ganciclovir-resistant CMV isolates and acyclovir-resistant HSV and VZV strains (see Table 295.4).[284] Foscarnet also is active against HIV. This antiviral agent directly inhibits DNA polymerase by blocking the pyrophosphate binding site and preventing cleavage of pyrophosphate from deoxynucleotide triphosphates.[285] Foscarnet is a noncompetitive inhibitor of viral DNA polymerases or HIV reverse transcriptase and is not incorporated into the growing viral DNA chain.

Foscarnet is approximately 100-fold more active against viral enzymes than against host cellular enzymes.[285] Resistance occurs as a result of DNA polymerase mutations. Strains of CMV, HSV, and VZV with threefold to fivefold reduced sensitivity to foscarnet have been reported.[286,287] These isolates may respond to therapy with acyclovir[286] or cidofovir.[287]

Pharmacokinetics.

Foscarnet is absorbed poorly after oral administration, with a bioavailability of about 20%.[284] This limits foscarnet administration to the intravenous route. Maximal serum concentration attained after a dose of 60 mg/kg is approximately 500 μmol/L. Data regarding tissue distribution are limited, but CSF concentrations are about two thirds of those in serum.[288]

Eighty percent of an administered dose of foscarnet is eliminated unchanged in the urine. The half-life is 48 hours, and dosage adjustments are necessary even for minimal degrees of renal dysfunction (see Table 296.6). The degree of dose reduction is proportional to the degree of reduction in CrCl; when CrCl is 50% of normal, the dose should be reduced by about 50% (Fig. 295.1). Hemodialysis efficiently eliminates foscarnet, and an extra dose of drug is recommended after dialysis for 3 or more hours.[289] There are no pharmacokinetic data for foscarnet in neonates.

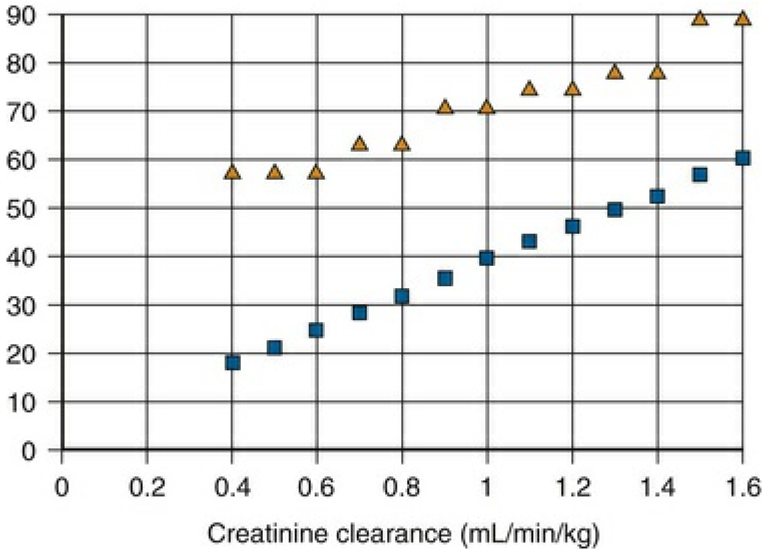

FIGURE 295.1 Recommended dosage of foscarnet for patients with various degrees of renal impairment. *Triangles* indicate the maintenance dose (mg/kg/day),

and *squares* indicate the induction dose (mg/kg/8 hr).

(Modified from MacGregor RR, Graziani AL, Weiss R, et al. Successful foscarnet therapy for cytomegalovirus retinitis in an AIDS patient undergoing hemodialysis: rationale for empiric dosing and plasma level monitoring. J Infect Dis 1991;164:785–787.)

Toxicity and Drug Interactions.

The most common and serious adverse effects are nephrotoxicity and metabolic derangements. Azotemia, proteinuria, acute tubular necrosis, crystalluria, and interstitial nephritis can occur,[290] and serum creatinine concentrations increase, usually during the second week of therapy, in as many as 50% of patients. In most affected patients, renal function returns to normal within 2 to 4 weeks after discontinuing foscarnet. Risk factors for developing renal dysfunction include preexisting renal disease, concurrent use of other nephrotoxic drugs, dehydration, rapid injection of large doses, and continuous intravenous infusion of drug.[291]

Drug-related electrolyte disturbances can occur, including symptomatic hypocalcemia, hypercalcemia, hypophosphatemia, and hyperphosphatemia. Hypocalcemia is caused by direct chelation of ionized calcium by the drug, and patients can have paresthesias, tetany, seizures, and arrhythmias.[292] Metabolic disturbances can be minimized if foscarnet is administered by slow infusion, with rates not exceeding 1 mg/kg/min.

Common drug-associated CNS symptoms include headache, tremor, irritability, seizures, and hallucinations. Fever, nausea, vomiting, abnormal serum hepatic enzymes, anemia, granulocytopenia, and genital ulcerations are reported. Genital ulcerations appear to be associated with high urinary concentrations of drug.[293] Concomitant use of amphotericin B, cyclosporine, gentamicin, and other nephrotoxic drugs increases the likelihood of renal dysfunction associated with foscarnet therapy. Hypocalcemia is more common with coadministration of pentamidine, and anemia and neutropenia are more common when patients are treated with foscarnet and zidovudine.

Clinical Uses and Recommended Dosage.

The most important indication for foscarnet is therapy for sight-threatening chorioretinitis caused by CMV in patients with AIDS.[284] Several controlled trials have demonstrated that foscarnet is as effective as ganciclovir in managing this infection and may offer a survival advantage because of its inherent activity against HIV.[290] In refractory cases of chorioretinitis, combination foscarnet and ganciclovir therapy have been given.[183] Foscarnet also is effective in the treatment of ganciclovir-resistant strains of CMV infections.[294] Limited data for patients with AIDS suggest a foscarnet benefit for gastrointestinal and pulmonary CMV infections.[164,226]

The usual dosage regimen for CMV infection is 180 mg/kg/day in 3 divided doses for 14 to 21 days, followed by a daily maintenance dose of 90 to 120 mg/kg. About 90% of patients have stabilization of their retinitis, and the time to progression of infection is prolonged to about 3 months.[295]

Infections caused by acyclovir-resistant strains of HSV and VZV have been successfully controlled with foscarnet.[296,297] The dosage of foscarnet used for these infections is 120 mg/kg/day in 3 divided doses. In patients with AIDS, foscarnet therapy should be initiated within 7 to 10 days of suspicion of infection caused by acyclovir-resistant HSV or VZV.[298] Therapy should be continued until lesions have resolved.

Neuraminidase Inhibitors

Oseltamivir Phosphate

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Oseltamivir (Tamiflu) is one of three licensed medications that specifically target the neuraminidase protein common to influenza A and B viruses. Oseltamivir is an ethyl ester prodrug that, after hydrolysis by hepatic esterases, is converted to the active compound, oseltamivir carboxylate. The prodrug masks the polarity of the active compound, allowing for enhanced oral bioavailability. The mechanism of action for this class of compounds is the specific inhibition of the influenza neuraminidase, with subsequent interference with the deaggregation and release of the viral progeny. The influenza neuraminidase enzyme is highly conserved and is common to influenza A/H1N1, A/H2N2, A/H3N2, and A/H5N1 and influenza B viruses. Antiviral activity in vitro is assay and strain dependent.

In human challenge studies, only 3% of posttreatment isolates were resistant to oseltamivir. Whereas a phase IV study from Japan identified neuraminidase mutations conferring resistance to neuraminidase inhibitors in 18% of treated children,[299] a prospective study in the United States documented a resistance rate of 4.4% among young infants treated with oseltamivir.[300]

Pharmacokinetics.

Oseltamivir has good oral bioavailability; at least 75% of orally administered drug reaches the systemic circulation in the form of oseltamivir carboxylate. The C_{max} and AUC for the active compound after a 75-mg (twice daily) oral dosing regimen are 348 ng/mL and 2719 ng•hr/mL, respectively. Coadministration with food has no significant effect on the peak plasma concentration. Neither oseltamivir nor oseltamivir carboxylate is metabolized by CYP450 isoforms. The rate of protein binding of oseltamivir carboxylate is only 3%, whereas the rate of protein binding of the prodrug is 42%.

The half-life of oseltamivir after oral administration is 1 to 3 hours, and the half-life of oseltamivir carboxylate is 6 to 10 hours.[301] The primary route of elimination of oseltamivir is by conversion to the active drug, with more than 90% of the prodrug metabolized to oseltamivir carboxylate. Oseltamivir carboxylate is not further metabolized, and it is eliminated entirely by renal excretion through glomerular filtration and anionic tubular secretion. Serum concentrations of oseltamivir carboxylate increase in the setting of declining renal function, and dose adjustment is recommended for patients with a CrCl value less than 30 mL/min. Administration of oseltamivir to patients with renal failure (CrCl <10 mL/min) has not been evaluated.

In infants younger than 1 year of age, an oseltamivir dose of 3 mg/kg produces adequate drug exposure in patients 0 to 8 months of age, although there is greater variation in infants younger than 3 months of age. In patients 9 to 11 months of age, a dose of 3.5 mg/kg is required.[300]

Toxicity and Drug Interactions.

The most common adverse effect reported is nausea with or without vomiting. In controlled clinical trials, approximately 10% of patients reported nausea without vomiting, and an additional 10% experienced vomiting. The nausea and vomiting episodes typically were mild to moderate and usually occurred on the first 2 days of oseltamivir administration. Fewer than 1% of study subjects discontinued participation in the clinical trials prematurely because of nausea or vomiting. Food may help to alleviate the gastrointestinal side effects in some patients.[302] Insomnia and vertigo also were reported more frequently among oseltamivir recipients than those receiving placebo.

No drug interactions have been described for oseltamivir or oseltamivir carboxylate. Neither the prodrug nor the active metabolite is metabolized by CYP450 isoforms. No dose adjustments are required when oseltamivir is coadministered with probenecid.

Clinical Uses and Recommended Doses.

Oseltamivir is licensed for the treatment and prophylaxis of influenza infection in patients ≥2 weeks of age.[300] The efficacy of oseltamivir for the treatment of influenza has been established in two large phase III studies, one conducted at 60 centers throughout the United States[303] and the other conducted at 63 centers in Europe, Canada, and China.[304] Of a total of 1355 patients enrolled in these two trials, 849 (63%) were confirmed subsequently to have influenza infection (95% with influenza A). Patients had to be enrolled within 36 hours of the onset of symptoms. The duration of illness among oseltamivir recipients was reduced by approximately 1.3 days compared with placebo recipients in both studies.[303,304]

Among patients treated within 24 hours of the onset of symptoms, illness duration was reduced by almost 2 days.[304] Oseltamivir recipients compared with patients receiving placebo also had a more rapid return to normal health and activity.[303] No serious drug-related adverse events were reported. Oseltamivir-associated nausea occurred in 17% and 12% of patients in the United States and international studies, respectively. The frequency of physician-diagnosed secondary complications leading to antibiotic prescriptions also was reduced among oseltamivir recipients.[305] Similar results were observed in a randomized, double-blind, placebo-controlled study enrolling children with influenza infection.[306]

Compared with placebo, administration of oseltamivir for 6 weeks during the peak of influenza season significantly reduced the risk of contracting influenza.[307] The protective efficacy for the prevention of culture-proven influenza approached 90%,[307,308] which is comparable with that achievable with amantadine and rimantadine for susceptible influenza A.

The recommended oral dose of oseltamivir for the treatment of influenza in people 13 years of age or older is 75 mg twice daily for 5 days. For children 1 through 12 years of age, dose is based on weight (≤15 kg [≤33 lb], 30 mg bid; >15–23 kg [>33–51 lb], 45 mg bid; >23–40 kg (>51–88 lb), 60 mg bid; >40 kg (>88 lb), 75 mg bid). Duration of treatment is 5 days. For infants between 2 weeks and 12 months of age, the approved dose is 3 mg/kg per dose given twice daily, although some experts recommend the dose of 3.5 mg/kg for infants 9 through 11 months old.[309] In premature neonates, the recommended oseltamivir dose is 1 mg/kg per dose given orally twice daily for neonates younger than 38 weeks' postmenstrual age; 1.5 mg/kg per dose administered orally twice daily for those 38 through 40 weeks' postmenstrual age; and 3 mg/kg per dose administered orally twice daily for those older than 40 weeks' postmenstrual age.[309] If possible, treatment should begin within 2 days of the onset of symptoms of influenza. Oseltamivir can be taken with or without food; tolerability may be enhanced when taken with food.

The recommended oral dose of oseltamivir for the prophylaxis of influenza in people 13 years of age or older is 75 mg given once daily for at least 7 days. Therapy should begin within 2 days of close contact with an infected person. Safety and efficacy have been demonstrated for up to 6 weeks.[307]

No dose adjustment is necessary for patients with CrCl values greater than 30 mL/min. In patients with a CrCl value of less than 30 mL/min, the dose of oseltamivir should be reduced to 75 mg given once daily for 5 days. Caution is advised when oseltamivir is administered to patients with CrCl values less than 10 mL/min because the use of the compound has not been evaluated in this population. Oseltamivir is licensed by the FDA for use only in adults for the treatment of influenza A and B infections.

Peramivir

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Peramivir (Rapivab) inhibits the influenza neuraminidase enzyme by mimicking the sialic acid residues of the cell membrane and binding to the neuraminidase active site, thereby competing with neuraminic acid. This interferes with de-aggregation and release of viral progeny. In addition to the carboxyl group that is present in oseltamivir and zanamivir, which binds to amino acids R118, R292, and R317, peramivir has two side chains that enable tight binding to the N9 neuraminidase site for more than 24 hours, followed by slow dissociation.[310,311]

Peramivir is active against influenza B viruses in vitro and in mice and ferrets,[312,313] with a single intravenous administration giving mice 100% protection. The mean neuraminidase inhibitory activity ± SD (i.e., IC_{50} values) of peramivir in biochemical assays against influenza A/H1N1 virus, influenza A/H3N2 virus, and influenza B virus clinical isolates collected between 2009 and 2012 by the WHO Global Influenza Surveillance and Response System (GISRS) were 0.17 ± 0.10, 0.18 ± 0.08, and 0.74 ± 0.33, respectively.[314]

Emergence of peramivir-resistant variants was detected after 15 passages in MDCK cells under drug pressure, and the mutant virus had an H274Y neuraminidase mutation that conferred a 714-fold reduction in susceptibility to peramivir.[315] In vivo, resistance among influenza A and B viruses to peramivir is uncommon, with 3.2% of influenza A/H1N1 viruses, less than 1% of influenza B viruses, and no influenza A/H3N2 viruses demonstrating resistance.[314] Peramivir resistance usually is associated with the H275Y neuraminidase amino acid substitution.[314,316,317] Cross-resistance between peramivir, oseltamivir, and zanamivir has been generated in vitro, but the clinical impact of this reduced susceptibility has not been elucidated.

Pharmacokinetics.

Peramivir use is limited to parenteral administration due to low oral bioavailability. The mean T_{max} after a 30-minute infusion of peramivir is approximately 30 to 40 minutes. The rate of human plasma protein binding is less than 30%. The terminal half-life after a 600-mg intravenous dose is approximately 20 hours, and the mean CrCl value is 122 mL/min.[318] Renal excretion is the only documented route of elimination of peramivir and its metabolites. In humans, peramivir is not significantly metabolized, and approximately 90% of administered peramivir is excreted unchanged in urine.

Hemodialysis removes 73% to 81% of peramivir. Peramivir also is cleared by continuous venovenous hemofiltration.[319] Dose reduction is recommended for CrCl values less than 50 mL/min. The peramivir exposures of children given a 10-mg/kg dose were within the range of exposures at which the efficacy and safety have been confirmed in adults.[320]

Toxicity and Drug Interactions.

Adverse events are diarrhea, nausea, vomiting, and decreased neutrophil count. Less common adverse events include dizziness, headache, somnolence, nervousness, insomnia, feeling agitated, depression, nightmares, hyperglycemia, hyperbilirubinemia, elevated blood pressure, cystitis, anorexia, and proteinuria.[321]

Peramivir does not inhibit or induce cytochrome P450 enzymes. No drug-drug interactions are observed with coadministration of rimantadine, oseltamivir, or oral contraceptives.

Clinical Uses and Recommended Doses.

Compared with placebo, a single intravenous dose of peramivir significantly decreases time to alleviation of symptoms and resumption of normal activities and hastens clearance of virus.[322] A single intravenous peramivir dose of 300 or 600 mg is noninferior to a 5-day course of oral oseltamivir, with median durations of influenza symptoms of 78, 81, and 81.8 hours in patients treated with 300 mg of peramivir, 600 mg of peramivir, and 75 mg twice daily of oseltamivir, respectively; both peramivir groups were noninferior to the oseltamivir group.[323] The higher dose of 600 mg of intravenous peramivir was superior to a 300-mg dose in adults with chronic medical conditions such as diabetes and chronic respiratory tract illnesses.[324] A postmarketing study from Japan assessed the efficacy of intravenous peramivir for influenza B infections and showed superiority to oseltamivir in reducing the duration of fever (1 vs. 3 days) in children 5 to 18 years old, but it found no difference in children younger than 9 years of age.[325]

The US peramivir labeling indication is for the treatment of acute uncomplicated influenza virus infection in patients at least 18 years of age who have been symptomatic for 2 days or less. The recommended dose is 600 mg administered by intravenous infusion over 15 to 30 minutes. Dose adjustment is required for significant renal impairment.

Zanamivir

Chemistry, Mechanism of Action, Spectrum, and Resistance.

Zanamivir (Relenza) interferes with the function of the influenza neuraminidase enzyme, causing subsequent interference with de-aggregation and release of the viral progeny. Zanamivir has poor oral bioavailability and therefore is administered by oral inhalation. Although the amount of zanamivir that is delivered to the respiratory tract during inhalation depends on patient factors such as inspiratory flow, the supplied delivery device delivers 4 mg of zanamivir when tested in vitro under conditions that approximate inhalation pressures achievable in vivo. Antiviral activity in vitro is assay and strain dependent.

Antiviral resistance can be induced in vitro by performing passage of the virus in the presence of increasing concentrations of zanamivir.[326,327] Decreased susceptibility is associated with mutations resulting in amino acid changes in the viral neuraminidase or hemagglutinin, or both. Resistance has been documented in clinical specimens isolated from a zanamivir recipient. After 2 weeks of therapy with zanamivir, an immunocompromised patient infected with influenza B shed a resistant isolate that had mutations in the viral hemagglutinin and neuraminidase.[328] The neuraminidase mutation resulted in a 1000-fold reduction in enzyme activity. Cross-resistance between zanamivir and oseltamivir has been demonstrated in resistant isolates generated in vitro. Accurate estimation of the risk of emergence of oseltamivir resistance in the clinical setting will be determined only by careful phase IV monitoring postlicensure.

Pharmacokinetics.

More than 75% of an orally inhaled dose of zanamivir is deposited in the oropharynx, most of which is swallowed. Approximately 13% of the dose distributes to the airways and lungs, and the remainder is retained in the delivery device.[329] Inhaled zanamivir provides local concentrations in respiratory tract mucosa that greatly exceed inhibitory concentrations for influenza A and B viruses[329,330]; median zanamivir concentration exceeds 1000 ng/mL in sputum 6 hours after inhalation and remains detectable for 24 hours.[331] Between 4% and 17% of an inhaled dose of zanamivir is absorbed systemically.

No metabolites of zanamivir have been identified, and all absorbed drug is excreted unchanged in the urine. Although serum zanamivir concentration increases with decreasing CrCl, no adjustment in dosing is necessary in cases of renal insufficiency. Unabsorbed drug is excreted in the feces.

Toxicity and Drug Interactions.

Zanamivir is well tolerated.[332] The most serious adverse event is respiratory distress, and decline in pulmonary function and bronchospasm have been reported in some patients.[333,334] Many of these patients had underlying disease of the airways such as asthma or chronic obstructive pulmonary disease. Although influenza can cause such deteriorations, zanamivir usually is not recommended for the treatment of patients with underlying airways disease because of the risk of adverse events and the lack of demonstrated efficacy in this population. Zanamivir should be discontinued in any patient who develops bronchospasm or a decline in respiratory function.

No drug interactions with zanamivir have been reported.[335] Zanamivir does not affect CYP450 isoenzymes in human liver microsomes.

Clinical Uses and Recommended Doses.

The efficacy of zanamivir in the management of influenza A and B virus infections has been demonstrated in three placebo-controlled studies.[336–338] A total of 1588 patients were enrolled in the three investigations; 1167 (73%) were infected with influenza. Patients received zanamivir (10 mg inhaled bid), which was compared with placebo inhaled twice daily. The zanamivir-treated patients improved 1 to 2.5 days faster than did the placebo recipients. Combined analysis of these trials indicated that zanamivir reduces the duration of symptoms by approximately 1.5 days.[334] Similar findings have been demonstrated in influenza-infected children.[339] Efficacy has been documented for both influenza A and influenza B.[340] Zanamivir therapy also reduces the frequency of antibiotic prescriptions for lower respiratory complications by 40%, although not for presumed upper respiratory tract complications.[341]

Inhaled zanamivir (10 mg once daily administered for 4 weeks) used as seasonal prophylaxis reduces the likelihood of laboratory-confirmed influenza infection (with or without symptoms) by 31%, influenza disease by 67%, and influenza disease with fever by 84%.[342] A study of zanamivir administered once daily to healthy household contacts of influenza-infected index subjects demonstrated a 79% reduction in influenza illness.[343]

Zanamivir is indicated for the treatment of uncomplicated illness due to influenza A and B virus. The recommended dose of zanamivir for the treatment of influenza in adults and children at least 7 years of age is two inhalations of 5 mg each administered twice daily for 5 days. Two doses should be taken on the first day of treatment if possible, provided that there is an interval of at least 2 hours between doses. On subsequent days, the doses should be approximately 12 hours apart. Patients scheduled to use an inhaled bronchodilator at the same time as zanamivir should use their bronchodilator before taking zanamivir. No dose adjustments are indicated in patients with impaired renal function.

Antiparasitic Agents

Edward T. Ryan

In this chapter, antiparasitic therapy is organized in five categories: agents active against luminal protozoans, agents active against the kinetoplastid protozoans, agents active against the malarial parasites, antibacterial agents with antiprotozoan activity, and anthelmintics. These divisions are somewhat arbitrary because some drugs are pertinent to more than one category. Appendix 296.1, which describes the drugs for parasitic infections, is arranged by organism. Appendix 296.2 provides the principal adverse effects of antiparasitic medications.

Recommended dosing indications for individual drugs can vary by organism. Most of the drugs, their indications for specific disease states, and recommendations for treatment and prophylaxis are discussed more extensively in pathogen-specific chapters.

A few drugs that are not available in the United States but are used extensively in other countries are discussed. Niclosamide, quinacrine, diloxanide furoate, furazolidone, and mebendazole no longer are commercially produced or distributed but may be available through specialized compounding pharmacies. Artesunate, benznidazole, diethylcarbamazine, eflornithine, melarsoprol, nifurtimox, sodium stibogluconate, and suramin are available only through the Centers for Disease Control and Prevention (CDC) (www.cdc.gov/laboratory/drugservice/formulary.html).

Because drug treatment recommendations are revised periodically, updated references should be consulted to obtain current recommendations. During weekdays, physicians with questions regarding the management of patients with parasitic diseases can call the CDC Parasitic Diseases Hotline (404-718-4245) or the CDC Malaria Hotline (770-488-7788; toll-free: 855-856-4713); both resources can be reached during nights and weekends at an alternate number (770-488-7100). Additional information is available at the CDC website (http://www.cdc.gov/parasites/health_professionals.html#drugs).

Treatment of Luminal Protozoa

Intestinal luminal protozoan parasites include *Giardia intestinalis*, *Cryptosporidium parvum* and *C. hominis*, *Cyclospora cayetanensis*, *Cystoisospora (Isospora) belli*, *Entamoeba histolytica*, *Entamoeba polecki*, *Dientamoeba fragilis*, and *Balantidium coli*. *Blastocystis* spp. (e.g., *hominis*) is of uncertain significance. *Trichomonas vaginalis* is a vaginal luminal protozoan.

Metronidazole and Tinidazole.

Metronidazole and tinidazole are synthetic nitroimidazoles with selective activity against organisms that use anaerobic metabolism. Metronidazole has been efficacious for the following protozoan infections: *E. histolytica, E. polecki, G. intestinalis, T. vaginalis, B. hominis,* and *B. coli.*[1–6] Tinidazole is approved for use against giardiasis and amebiasis in adults and children older than 3 years of age and for trichomoniasis in adults.[7] For amebiasis, these drugs are active against the trophozoite stage of the parasite life cycle and can be used to treat the luminal and tissue phases of the infection, including liver abscesses. Patients with invasive colonic disease or liver abscess also are treated with paromomycin or iodoquinol or other luminally active amebicides to eliminate residual luminal forms of the parasite.

Metronidazole and tinidazole are the only effective therapies available in the United States for trichomoniasis.[8] Both drugs are effective against giardiasis. Tinidazole is as effective as metronidazole for most clinical indications and is modestly better tolerated. Tinidazole is used as a single-dose regimen for giardiasis and trichomoniasis, and the recommended course for amebiasis is shorter. Despite this, a course of tinidazole is considerably more expensive than generic metronidazole for all indications.[7]

Tinidazole is not available in suspension, but it can be formulated by crushing the tablets.

Metronidazole and tinidazole are well tolerated; tinidazole is modestly better tolerated compared with metronidazole at the high single-dose regimens or at the higher doses used for amebiasis. Side effects of both drugs include nausea, vomiting, epigastric discomfort, anorexia, and a metallic or bitter taste. Seizures and peripheral neuropathy have been reported uncommonly with both drugs. Patients taking either drug should avoid alcohol (including that found commonly in suspensions of children's medicines) because of the disulfiram-like effects.

Furazolidone.

Furazolidone is a nitrofuran derivative most commonly used in the treatment of giardiasis in children because of its availability in a liquid preparation. It is no longer commercially available in the United States.

The gastrointestinal tract side effects of nausea and vomiting are the most common complaints associated with furazolidone therapy. Allergic reactions, including pulmonary infiltration, hypotension, urticaria, fever, and vesicular rash, occur occasionally. Other potential complications of furazolidone therapy are a disulfiram-like reaction with concurrent use of alcohol-containing medications, hemolytic anemia either in infants younger than 1 month of age or in patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency, and reactions due to the drug's monoamine oxidase inhibitor activity.

Nitazoxanide.

Nitazoxanide is a nitrothiazolyl-salicylamide derivative, whose activity appears to be at the level of electron transfer of anaerobic metabolism.[9] It has broad activity against protozoa, anaerobic bacteria, and helminths. It is the drug of choice for treating patients with cryptosporidiosis, and it is effective against giardiasis, blastocystiasis, fascilosiasis, and hymenolepsiasis; the latter two are worm infections.[9–16] Nitazoxanide usually is well tolerated.

Iodoquinol.

Iodoquinol (i.e., diiodohydroxyquin) is a halogenated oxyquinoline.

It is a luminally active agent with efficacy against *E. histolytica, D. fragilis, B. hominis,* and *B. coli.*[17]

The mechanism of action of iodoquinol is poorly understood. The drug is poorly absorbed and therefore reaches high concentrations in the lumen of the colon. Gastrointestinal tract complaints, including nausea, cramps, and diarrhea, are the most common problems associated with therapy. Other side effects occasionally associated with its use are rash, acne, anal pruritus, and slight enlargement of the thyroid gland.

Diloxanide Furoate.

A dichloroacetamide derivative of an acetanilide, diloxanide furoate has amebicidal activity at low concentrations. It is a luminally active agent with activity against *E. histolytica* and *E. polecki.* Diloxanide furoate has no activity against the extraluminal forms of *E. histolytica.* Its only common side effect is flatulence; nausea, vomiting, and diarrhea are occasional side effects. The drug is well tolerated and inexpensive, but it is not commercially available in the United States.

Paromomycin.

Paromomycin, an aminoglycoside, is poorly absorbed by patients with an intact gastrointestinal tract and is active as a luminal agent for *E. histolytica, D. fragilis,* and *G. intestinalis.* Paromomycin is not active against the extraluminal forms of *E. histolytica.* The use of paromomycin for giardiasis is limited but may be indicated for treatment of giardiasis during pregnancy because it is poorly absorbed. The frequent side effects of paromomycin with oral use are gastrointestinal tract disturbances, which are self-limited.

Treatment of Kinetoplastidea Infections

Kinetoplastidal infections include those caused by *Trypanosoma,* including American trypanosomiasis caused by *T. cruzi* (i.e., Chagas' disease), African trypanosomiasis (i.e., sleeping sickness) caused by *T. brucei rhodesiense* (i.e., East African trypanosomiasis) and *T. brucei gambiense* (i.e., West African trypanosomiasis), and leishmaniasis caused by a range of species. Several drugs used to treat people with these infections are available in the United States only through the CDC.

Suramin.

Suramin sodium is a nonmetallic compound developed in the 1920s on the basis of structural similarities to trypanocidal dyestuffs. Suramin is active against the hemolymphatic stages of African trypanosomes (i.e., *T. brucei rhodesiense* and *T. brucei gambiense*), and it has been used prophylactically for workers in areas where *T. brucei gambiense* is highly endemic.

Suramin is available from the CDC and only in a parenteral formulation. The side effects of suramin are protean and can be life-threatening. Frequently encountered side effects include vomiting and acute hypersensitivity-like reactions (i.e., pruritus, urticaria, paresthesias, hyperesthesia of hands and feet, and photophobia), and later effects include neurologic, ocular, renal, and hepatic toxicities. Arsenic-based compounds or eflornithine are recommended for trypanosomiasis involving the central nervous system.

Melarsoprol.

Melarsoprol, a trivalent antimonial compound, is used exclusively for treatment of central nervous system trypanosomiasis caused by *T. brucei rhodesiense.*[18,19] It is available only from the CDC and in a parenteral formulation.

Severe side effects are common and include fever, vomiting, a delayed drug-induced reactive encephalopathy (which is potentially fatal), myocardial damage, albuminuria, hypertension, colic, Herxheimer-type reaction, and peripheral neuropathy. Many other toxic effects include gastrointestinal tract complaints, hypersensitivity reactions, renal and hepatic dysfunction, and a severe hemolytic anemia in G6PD-deficient patients. Because of these effects, eflornithine has become the drug of choice for central nervous system trypanosomiasis caused by *T. brucei gambiense.*

Eflornithine.

Eflornithine (i.e., difluoromethylornithine [DFMO]) is an irreversible inhibitor of the enzyme ornithine decarboxylase and is active preferentially against many protozoan parasites. Eflornithine is a drug of choice, alone or in combination, to treat people with African sleeping sickness caused by *T. brucei gambiense*, including those with advanced central nervous system disease.[20–22]

Eflornithine has limited side effects compared with other available agents, but its use in endemic areas is limited by its cost and labor-intensive administration. East African sleeping sickness caused by *T. brucei rhodesiense* is less responsive to this therapy. Eflornithine causes mild reversible bone marrow toxicity (manifested by anemia, leukopenia, and occasionally, thrombocytopenia) diarrhea, seizures, and occasional transient hearing loss. Eflornithine is available from the CDC.

Benznidazole.

Benznidazole is a 2-nitroimidazole derivative that inhibits protein and ribonucleic acid synthesis. It is used in the treatment of patients infected with *T. cruzi* (i.e., Chagas disease).[23,24] Benznidazole usually is better tolerated and may be more effective than nifurtimox, but side effects are common and include rash, neuropathy, intestinal disturbances, and neuropsychiatric alterations. Therapy is prolonged (60 days). Benznidazole is available from the CDC.

Nifurtimox.

Nifurtimox is a nitrofuran with activity against African and American (i.e., *T. cruzi*) forms of trypanosomiasis.[25] The efficacy of nifurtimox for the chronic forms of Chagas disease appears to be more geographically variable, with better results in Chile, Venezuela, Argentina, and southern Brazil than in central Brazil.

Therapy with nifurtimox usually is prolonged, and another agent commonly is substituted because of toxicity. Toxic effects of nifurtimox usually are reversible. They include gastrointestinal tract symptoms (e.g., anorexia, vomiting), weight loss, memory loss, sleep disorders, weakness, and nervous system disorders (e.g., tremor, paresthesias, polyneuritis, convulsions [rare]). Other rare complications are fever, pulmonary infiltrates, and pleural effusion. Children usually tolerate therapy better than adults.

Sodium Stibogluconate.

Sodium stibogluconate and meglumine antimonate are synthetic, pentavalent antimonial agents. They are used to treat patients with leishmaniasis, although other agents have replaced them as drugs of choice. These compounds probably are as active against leishmaniasis as the trivalent antimonial agents and usually are better tolerated.

Side effects of sodium stibogluconate include gastrointestinal tract complaints (i.e., nausea and diarrhea), musculoskeletal complaints (i.e., muscle and joint pain), fatigue, serum transaminase elevations, T-wave inversion or flattening, pancreatitis, and rarely, myocardial, renal, and hepatic damage. Sodium stibogluconate is available from the CDC.

Pentamidine.

A diamidine, pentamidine is effective as a second-line agent for cutaneous leishmaniasis and for the hemolymphatic stages of African trypanosomiasis.[26] Pentamidine is used most commonly in the United States as a second-line agent for treatment or prophylaxis of *Pneumocystis jirovecii* infections.[27] Originally considered a protozoan, *Pneumocystis* species now are classified as fungi.

Pentamidine is available in a parenteral preparation or as aerosolization therapy for *P. jirovecii* infections. A high incidence of side effects is associated with the parenteral administration of pentamidine. Adverse effects include hypoglycemia, hyperglycemia, pain at the injection site, hypotension, gastrointestinal tract disturbances (including vomiting), reversible nephrotoxicity, elevated serum transaminase levels, electrolyte disturbances, and bone marrow toxicities. Less common toxicities are anaphylaxis, acute pancreatitis, hyperkalemia, and cardiotoxicity. Pentamidine should not be used concurrently with didanosine, foscarnet, nephrotoxic drugs, or erythromycin because it can potentiate these agents' toxicities. There are few systemic side effects with the aerosolized therapy, although bronchospasm is common, as is difficulty delivering this therapy effectively to younger children.

Liposomal Amphotericin and Amphotericin B.

Liposomal amphotericin is the drug of choice in the United States for the treatment of patients with visceral leishmaniasis. It is an alternative agent for patients with mucosal leishmaniasis, and it can also be used in patients with extensive cutaneous disease.[28–32] Amphotericin B can be used, but it is more toxic, has lower efficacy, and requires more prolonged therapy than liposomal amphotericin.

Miltefosine.

Miltefosine is an oral agent that can be used to treat patients with visceral, mucosal, or cutaneous leishmaniasis.[30,33–41] Its mechanism of action is unknown. It is a synthetic ether phospholipid analogue that is chemically similar to phospolipids in cell membranes. It also has immunomodulatory effects. Side effects include intestinal disturbances, motion sickness, and elevated creatinine levels.

Although miltefosine has the advantage of being an oral agent, its use predominantly has been evaluated against New World leishmanial strains (i.e., cutaneous and mucosal) and Old World visceral *L. donovani*, and it may be less effective than other agents. The US Food and Drug Administration (FDA)–approved indications are limited to infections with certain *Leishmania* species and to patients 12 years of age or older who weigh at least 30 kg and are not pregnant or breastfeeding.

Antimalarial Therapy

Human malaria can be caused by *Plasmodium falciparum*, *P. vivax*, *P. ovale*, *P. malariae*, and the zoonotic *P. knowlesi*. The optimal choice of antimalarial agents is based on the infecting species, drug resistance, and status of the host (i.e., complicated vs. uncomplicated malaria). If the species and drug resistance profile are unknown, treatment should target chloroquine-resistant *P. falciparum*. Those with severe or complicated malaria should be treated with parenteral agents. Treatment assistance is available through the CDC Malaria Hotline provided earlier.

Artemisinins.

Antimalarial treatment has evolved over the past decade. The World Health Organization (WHO) recommends that the first-line treatment of patients with chloroquine-resistant *P. falciparum* malaria should be artemisinin based. Artemisinin derivatives include artesunate, artemether, and dihydroartemisinin. Due to the short half-life and risk of drug resistance, these agents should be used in combination, which usually includes a rapid-acting artemisinin derivative and a longer-acting second agent. Combinations include artemether plus lumefantrine, artesunate plus mefloquine, artesunate plus amodiaquine, and dihydroartemisinin plus piperazine. In the United States, an oral combination of artemether–lumefantrine is FDA approved and commercially available.[42–44] Intravenous artesunate is avaliable from the CDC for the treatement of patients with severe or complicated malaria.

Artemisinins result in rapid decrease in parasite burden. Artemisinins also affect blood stage gametocytes and can decrease the risk of transmission. Artemisinins are not effective as prophylaxis against malaria. Unfortunately, decreased parasite clearance and emerging drug resistance is being reported in Southeast Asia. Artemisinins typically are well tolerated. Artensuate has been associated with a neurologic alterations and QTc prolongation, but it is much better tolerated than the other parenteral alternative (i.e., quinidine gluconate) for the treatment of patients with severe or complicated malaria. Artesunate also has been associated with a delayed hemolytic anemia. Artemether-lumefantrine usually is well tolerated, with intestinal disturbances, rash, and neurologic alterations reported occasionally. Lumefantrine can prolong the QTc.

Chloroquine.

Chloroquine, a 4-aminoquinoline, inhibits polymerization of ferriprotoporphyrin IX, resulting in oxidative membrane damage and death of the parasite in side of infected erythrocytes. Due to widespread resistance, its use in treating patients with malaria usually is reserved for cases when chloroquine susceptibility can be ensured. *P. falciparum* malaria is almost always choloroquine resistant, although cases acquired in Haiti are a notable exception. Extensive reports of chloroquine treatment failures with *P. vivax* have been reported from Papua New Guinea and Indonesia along with sporadic reports from Brazil, Myanmar, India, Guyana, and Colombia.[45,46] Otherwise, most cases of malaria due to *P. vivax, P. malariae,* or *P. ovale* remain responsive to chloroquine.

Chloroquine is active only against the erythrocytic stages of the parasite; another agent (i.e., primaquine) is necessary for the radical cure of *P. vivax* and *P. ovale* infections. Chloroquine has been used as adjunctive therapy with dehydroemetine for invasive amebiasis unresponsive to initial therapy and for therapy of connective tissue autoimmune diseases unresponsive to other agents.

Chloroquine is well tolerated by most people, even for long-term therapy. The side effects include mild gastrointestinal tract complaints (which are usually alleviated if the drug is taken with meals), occasional headaches, blurred vision, dizziness, fatigue, confusion, depigmentation of hair, skin eruptions, corneal opacity, weight loss, and myalgias. Intense pruritus, a common complaint among black Africans taking the drug, usually is relieved with antihistamines. Chloroquine is contraindicated in patients with psoriasis, retinal disease, or porphyria.

The preparations of chloroquine available in the United States are bitter-tasting tablets. Hydroxychloroquine is better tolerated by children. Suspensions of chloroquine are widely available elsewhere for pediatric use and are much better tolerated. Chloroquine can be used as a malarial chemoprophylactic.

Quinine.

Quinine, a *Cinchona* alkaloid, was the first commercially available antimalarial agent. Its use was supplanted when chloroquine became available. Mostly known for its antimalarial effects, quinine also is effective when used in combination with clindamycin for the treatment of babesiosis.

Until artemisinins became widely available, oral quinine sulfate in combination with pyrimethamine-sulfadoxine, tetracycline, or clindamycin was the recommended therapy for *P. falciparum* malaria acquired in areas of chloroquine resistance. For patients unable to take oral medication or with severe or complicated malaria, and if intravenous artesunate is unavailable, intravenous quinidine gluconate may be used as an alternative agent because of its relative safety compared with intravenous quinine hydrochloride.[47]

Quinine commonly causes side effects known collectively as cinchonism, which in the mild form consists of tinnitus, impaired vision, headache, nausea, and abdominal pain and in its more severe form, consists of cardiovascular, gastrointestinal, and dermal manifestations. Blood glucose levels must be monitored carefully in any patient receiving quinine because hypoglycemia occurs commonly, particularly in the setting of high parasitemia. An idiosyncratic hypersensitivity reaction to quinine also can occur, most commonly manifesting as extensive skin flushing with an intense, generalized pruritus; it is a contraindication to further use of the drug.

Quinidine.

Quinidine, the dextrostereoisomer of quinine, is an alternative agent for the treatment of patients with severe or complicated malaria if intravenous artesunate is not available.[47] Use of intravenous quinidine requires careful cardiac monitoring, often in an intensive care setting, due to its marked ability to prolong the QTc and its arrhythmogenic potential. Additional side effects include those associated with cinchonism. Patients requiring intravenous therapy should be changed to oral therapy as soon as tolerated.

Mefloquine.

Mefloquine is a 4-quinolinemethanol analogue of quinine. It was historically used for chemoprophylaxis or treatment of malaria.[48] Its use was associated with neuropsychiatric, vestibular, and sleep disturbances, and mefloquine received a Black Box label from the FDA in 2014. Drug resistance also has developed in areas of Southeast Asia. For these reasons, mefloquine has largely been supplanted by other agents, although it is the only agent available for weekly dosing for chemoprophylaxis in areas of the world with chloroquine resistance. It has the most established safety record for chemoprophylaxis in pregnant women, although data on use in the first trimester are limited.

Primaquine.

An 8-aminoquinoline, primaquine is the only drug available for treating the latent hepatic life cycle forms of *P. vivax* and *P. ovale*.[49,50] Primaquine is recommended for the radical cure of these infections after chloroquine treatment has been initiated for the erythrocytic stages of infection.

Primaquine usually is well tolerated except in people with G6PD deficiency, in whom administration can lead to brisk hemolysis. Patients should be screened for G6PD deficiency before primaquine therapy. Primaquine should never be used in pregnant women, regardless of G6PD status. Occasional side effects are neutropenia, gastrointestinal tract disturbance, and methemoglobinemia. Relapses of *P. vivax* after primaquine therapy have responded to repeat treatment with chloroquine and higher doses or more prolonged courses of primaquine.[51]

Atovaquone.

Atovaquone, a hydroxynaphthoquinone, is a ubiquinone analogue that has been studied most extensively as an antimalarial agent. Atovaquone was released in the United States for the treatment of *P. jirovecii* and *Toxoplasma gondii*.[52,53] Atovaquone is approved by the FDA in a fixed-dose combination with proguanil (i.e., Malarone in adult and pediatric dosages) for treatment and prophylaxis of *P. falciparum* infections.[54,55]

Atovaquone was combined with proguanil because of rapid development of resistance in vitro and in early clinical trials when atovaquone was used alone for malaria. Many studies have documented efficacy of the combination for the treatment and prophylaxis of *P. falciparum* malaria, and there is a growing experience in the treatment of infections with *P. vivax*.[56] The combination of atovaquone and azithromycin is an effective treatment for babesiosis with a better side effect profile than clindamycin plus quinine.[57]

For *P. jirovecii*, studies have indicated that atovaquone is slightly less efficacious but is tolerated moderately better than trimethoprim-sulfamethoxazole or pentamidine.[58] There are no efficacy data for children, but the pharmacokinetic data are similar to those for adults. The most common side effects are fever, nausea, diarrhea, and rashes. Unlike most of the currently used therapies, atovaquone is active against the tissue cyst stages of *T. gondii* in animal models. Atovaquone has been used alone or in combination with pyrimethamine for treatment of central nervous system toxoplasmosis in AIDS patients.[59]

Antibacterial Agents With Antiprotozoan Activity

Tetracycline and Doxycycline.

Agents with antiprotozoan activity increasingly have been used as antimalarial compounds, mainly in areas where drug-resistant malaria is a problem. When used for treatment, these compounds should always be given in combination with more rapidly acting drugs because they are slowly malariacidal. The drugs usually are well tolerated, except for common gastrointestinal tract complaints.

Photosensitivity and secondary *Candida* vaginitis are concerns with prolonged prophylactic use of doxycycline. Use of this class of compounds is restricted in pregnancy and usually in children younger than 8 years of age because of potential toxicity. Tetracycline also is efficacious for treatment of balantidiasis and can be used as adjunctive therapy with metronidazole to treat amebiasis.

Clindamycin.

Clindamycin is a macrolide antibiotic, which can be used in combination with other therapies for treatment of *P. falciparum* malaria, toxoplasmosis, and babesiosis. Clindamycin plus pyrimethamine is effective as an alternative treatment for *Toxoplasma* encephalitis in patients infected with human immunodeficiency virus (HIV) who cannot tolerate sulfadiazine.[60] Clindamycin plus quinine (or quinidine) is a recommended therapy for babesiosis, although atovaquone with azithromycin has better side effect profile.[57,61] Clindamycin has been used in combination with primaquine for the treatment of *P. jirovecii* infection in selected patients.[62] Clindamycin usually is well tolerated in children, but the unpleasant smell and taste of the solution make crushing the tablets a better option in some cases.

Spiramycin.

Spiramycin is a macrolide antibiotic used more extensively in Europe for the treatment of toxoplasmosis in pregnancy. Spiramycin has been used in the United States for the treatment of congenital toxoplasmosis in patients who are intolerant of other therapies. The drug usually is well tolerated and is available as an investigational drug from the manufacturer after approval from the FDA (phone: 301-796-1600). Occasional side effects are gastrointestinal tract disturbances.

Folate Metabolism Inhibitors.

Many antiprotozoan compounds take advantage of reliance of a parasite on the synthesis or scavenging of folate precursors. These compounds include the dihydrofolate reductase (DHFR) inhibitors, which preferentially inhibit the parasite enzyme, and sulfonamides, which act as *p*-aminobenzoic acid analogues and inhibit or act as suicide substrates in the folate biosynthetic pathways. These two classes of compounds often are formulated in combinations for various indications. DHFR inhibitors used for antiparasitic therapy include pyrimethamine, trimethoprim, proguanil, and trimetrexate. The sulfonamides have various pharmacokinetic properties, which are taken advantage of in the formulations used for treatment of parasitic infections.

Pyrimethamine with sulfadiazine is the treatment of choice for toxoplasmosis in most clinical settings. A limiting factor in HIV-infected patients who require prolonged therapy for toxoplasmosis is the high incidence of side effects, mainly attributed to the sulfonamide component. Pyrimethamine has been used with clindamycin in this clinical setting to circumvent these problems.[60] Supplementation with folinic acid often is recommended with prolonged use of pyrimethamine to lessen the bone marrow–suppressive effects of this drug and to prevent folic acid deficiency.

Trimethoprim-sulfamethoxazole, commonly formulated in a 1 : 5 ratio, is the treatment and prophylaxis of choice for *P. jirovecii* infections in HIV-infected patients and patients receiving immunosuppressive therapy.[63] The only limitation of this regimen is the high incidence (up to 65%) of untoward reactions in HIV-infected patients.[64] Trimethoprim plus dapsone is efficacious for *P. jirovecii* prophylaxis, although toxicity remains a problem.

Trimethoprim-sulfamethoxazole is the recommended therapy for any patient with *Cystoisospora belli* infection, although relapse is common among patients with AIDS.[65] Trimethoprim-sulfamethoxazole also has efficacy for *Cyclospora cayetanensis* infections in HIV-infected patients.[66,67] Trimethoprim-sulfamethoxazole has been used for the treatment of toxoplasmosis, but pyrimethamine-sulfadiazine should be considered the treatment of choice. It also has been used for prophylaxis against *T. gondii* in patients with AIDS who test positive for antibodies to *T. gondii* and have a 25% to 50% risk for toxoplasmic encephalitis.

Proguanil, the prototype of the DHFR inhibitors, is not available as a stand-alone agent in the United States, but it is available overseas. Proguanil has been approved by the FDA in a fixed-dose combination with atovaquone for the treatment and prophylaxis of infections with *P. falciparum.* Toxicity is a problem with combinations of DHFR inhibitors and sulfonamides, particularly in patients with AIDS. Most of these untoward reactions are attributed to the sulfonamide components of the combination. Common side effects of sulfonamides are rashes, fever, bone marrow suppression, gastrointestinal tract complaints, and hepatotoxicity. More severe but less common reactions include toxic epidermal necrolysis, Stevens-Johnson syndrome, erythema multiforme, and serum sickness. The toxicity most commonly associated with the DHFR inhibitors is bone marrow suppression, which usually can be alleviated by folinic acid supplementation. Proguanil also is associated with oral ulcerations, hair loss, scaling of palms and soles, and urticaria.

Treatment of Helminthic Infections

Helminths are multicellular worms that can be round (i.e., nematodes), flat (i.e., cestodes and tapeworms), or fluke-like (i.e., trematodes). Common roundworm infections include ascariasis, hookworm infection, trichuriasis (i.e., whipworm), enterobiasis (i.e., pinworm) strongyloidiasis, filariasis, and cutaneous and larval migrans. Common flatworm infections include taeniasis, cysticercosis, and diphyllobothriasis. Common trematode infections include schistosomiasis, fascioliasis, and paragonimiasis. Most helminth infections can be treated with one of three highly efficacious and safe drugs: albendazole, ivermectin, or praziquantel.

Intestinal Nematodes

Albendazole.

Albendazole is a synthetic nitroimidazole with a broad spectrum of antinematodal activity similar to that of mebendazole but with anticestodal and some antiprotozoal action. Mebendazole is no longer manufactured in the United States, and its use has been supplanted by albendazole. The advantage of albendazole over mebendazole is its activity in a single oral dose of 400 mg (200 mg for children <2 years old) against ascariasis, hookworm infection, trichostrongylosis, and to a slightly lesser extent, enterobiasis and trichuriasis.[68,69]

Because intestinal helminthiasis typically is multiparasitic, albendazole is an almost ideal agent.[70,71] It has good activity in multiple doses against cutaneous larva migrans and strongyloidiasis, but single-dose therapy with ivermectin is more effective for these two helminthic infections.[72,73] Successful treatment with albendazole of visceral larva migrans has been reported, although ivermectin is the drug of choice.[74] Efficacy against the microfilarial stage of *Wuchereria bancrofti, Brugia malayi,* and *Loa loa* is well documented, although diethylcarbamazine (DEC) remains the parasite adulticidal drug of choice for the treatment of patients with these filarial infections.[75–77] DEC plus albendazole in combination has superior activity against adult *W. bancrofti* compared with either drug alone.[78] Albendazole may be of benefit in patients with gnathostomiasis, baylisascariasis, trichinellosis, toxociariasis, capillariasis, and angiostrongyliasis.

Prolonged high-dose regimens of albendazole constitute the most effective medical treatment of larval cestode disease caused by *Echinococcus granulosus, E. multilocularis,* and *E. vogelii.*[79] Dosage is not defined for children younger than 6 years of age. Treatment is tailored to response and normally is required for a minimum of several weeks or months. Albendazole should be started several days before surgery to minimize the effect of intraoperative spillage of cyst contents. Albendazole also is used in the treatment of patients with cysticercosis, often with concomitant steroids.[80–82]

Albendazole binds irreversibly to the nematodal isoform of β-tubulin, blocking microtubule assembly, disrupting tegumental integrity, inhibiting motility, and impeding glucose uptake by the worm. Detectable levels are achieved in serum, cerebrospinal fluid, cyst fluid, and bile, with a serum half-life of 8 to 15 hours depending on the dose. Rapid, extensive hepatic biotransformation to the active metabolite, albendazole sulfoxide, occurs, but the major route of excretion is not clear.

Side effects of low-dose albendazole therapy are minimal, consisting of diarrhea, abdominal pain, migration of *Ascaris* through the mouth or nose, and rare hypersensitivity. With high-dose or prolonged therapy, elevated levels of hepatic transaminases, dizziness, neutropenia, and alopecia are most common.[83] Serum hepatic enzyme levels and the blood count should be monitored every 2 weeks during high-dose therapy.

Lack of data for children younger than 2 years of age has precluded specific US labeling for or establishment of dosage for this age group, although the label leaves the physician discretion in electing to treat children younger than 2 years of age. The pediatric dosage is identical to the adult dosage. Embryotoxic potential usually precludes the use of albendazole during pregnancy.

Albendazole is manufactured as a suspension and as tablets that can be crushed with food, chewed, or taken whole. Albendazole is poorly absorbed and should be ingested with food, preferably a fatty meal, to maximize absorption.

Pyrantel Pamoate.

Pyrantel pamoate, a broad-spectrum anthelmintic drug, is available only as an over-the-counter oral suspension in the United States. This drug has been supplanted by the benzimidazoles, except for its continued popularity for the treatment of enterobiasis. A single-dose regimen is sufficient for ascariasis and trichostrongylosis, but one dose daily on 3 consecutive days is required for hookworm infection. Pyrantel pamoate is ineffective for trichuriasis.

The agent is nonvermicidal but causes depolarizing neuromuscular blockade of helminth musculature. Paralyzed worms are expelled with intestinal peristalsis. Because of poor absorption from the gastrointestinal tract, side effects are restricted to infrequent occurrence of abdominal pain, diarrhea, dizziness, insomnia, rash, and headache. Pyrantel pamoate should be used with caution in people with hepatic dysfunction. Although no specific data exist on its use in children younger than 2 years of age, no age-related problems have been documented. Few data exist on use in pregnancy, and pyrantel pamoate is nonembryotoxic in animals. If absolutely necessary, it can be used after the first trimester of pregnancy. Pyrantel pamoate should not be administered concurrently with piperazine.

Systemic Nematodes

Diethylcarbamazine.

DEC is a piperazine derivative used primarily in the treatment of selected human filarial infections. Because of frequent unacceptable side effects in people infected with *Onchocerca volvulus,* DEC should not be used for microfilaricidal treatment of this parasite; ivermectin is the drug of choice. DEC is ineffective against *Mansonella* spp. and should not be used to treat visceral larva migrans.

For lymphatic filariasis (i.e., *W. bancrofti, Brugia malayi,* and *B. timori*) and loiasis, relatively low-dose microfilaricidal regimens are often used in the developing world as part of mass treatment campaigns. In the treatment of an individual patient, however, the aim is macrofilaricidal activity with the use of multiple aggressive courses of therapy.[84] Dosage regimens are not well established for children, but infection is rare in children younger than 2 years of age. Prophylactic use of weekly DEC for loiasis is effective.[85]

DEC, which should be taken after a meal, is absorbed readily, is distributed into all body compartments, and undergoes renal excretion with a serum half-life of 8 hours. The mechanism of action is not documented clearly.

Side effects, which often correlate with microfilarial load, most commonly include nausea, dizziness, headache, visual disturbances, and fever. Transient microscopic hematuria is common.[86] The gastrointestinal tract side effects are dose related, and some patients cannot tolerate the dose of 9 mg/kg/day. In patients with lymphatic filariasis, the death of adult worms often results in lymphadenopathy or lymphangitis, frequently in the genital region. Encephalopathy can occur after treatment for loiasis in people with high microfilarial counts.[87]

Ivermectin.

Ivermectin, a semisynthetic lactone originally developed in the

1970s for veterinary use, has broad activity against larval roundworms and a number of arthropods. Receptor-mediated hyperpolarization of cells after an influx of negatively charged ions occurs through a novel glutamate-sensitive chloride channel in nematodes. The drug is well absorbed when taken orally, and excretion is almost entirely in feces. It has a serum half-life of 12 hours.

Originally developed for human use in cases of onchocerciasis, ivermectin has become the treatment of choice for *O. volvulus* in a single microfilaricidal dose. Ivermectin is also the drug of choice for strongyloidiasis, cutaneous larval migrans, and scabies, and it can be used as an alternative agent for pediculosis.[88] Ivermectin is also microfilaricidal for *W. bancrofti, B. malayi,* and *L. loa.*

Ivermectin is remarkably nontoxic. Adverse effects are caused by reactions to the release of endosymbiotic bacteria from dying parasites.[89] This Mazzotti-type reaction can occur in onchocerciasis and filariasis and consists of fever, pruritus, urticaria, headache, myalgia, joint and bone pain, and tender lymphadenopathy.[90] The severity of the reaction usually is proportionate to the microfilarial load and rapidity of death of microfilariae. Reactions are less marked in *B. malayi* infection, in which microfilarial clearance occurs over days rather than hours. In lymphatic filariasis and loiasis, the severity of adverse effects with ivermectin is equivalent to those found with DEC. Ivermectin should not be used in patients who have loiasis with more than 5000 microfilariae per 1 mL of blood, and all patients with microfilaremic loiasis require premedication with corticosteroids. Adverse outcomes have not been observed for women accidentally treated while pregnant, but use in pregnancy is not recommended.

Trematodes and Cestodes

Praziquantel.

Praziquantel is the drug of choice for all fluke infections except for *Fasciola hepatica* (i.e., sheep liver fluke) and for all definitive host cestode infections.[91] It is effective for all species and clinical manifestations of schistosomiasis, including central nervous system disease.[92] For liver and intestinal flukes including *Clonorchis sinensis* (i.e., Chinese liver fluke), *Opisthorchis viverrini* (i.e., liver fluke), *Fasciolopsis buski* (i.e., intestinal fluke), *Heterophyes heterophyes* (i.e., intestinal fluke), *Paragonimus westermani* (i.e., lung fluke), and *Metagonimus yokogawai* (i.e., intestinal fluke), multidose therapy is required.

A single dose of praziquantel is an effective treatment for adult stages of the tapeworms *Taenia saginata* (i.e., beef), *T. solium* (i.e., pork), and *Diphyllobothrium latum* (i.e., fish). Although it is more expensive and is absorbed systemically, single-dose praziquantel offers the advantage over niclosamide of not requiring purging and of theoretically guarding against cysticercosis. Praziquantel can be used in patients with cysticercosis, and it is often given perioperatively in patients undergoing surgery for cystic echinococcosis.

Praziquantel is a heterocyclic prazinoisoquinoline derivative, and the precise mechanism of action is unknown. The agent is rapidly taken up by helminths, with resultant loss of intracellular calcium that causes blebbing and bursting of the tegument. Exposure of worm antigens in this way may allow the host immune system to play a role in final parasite death.

Oral absorption is rapid, with extensive first-pass metabolism by the liver. High levels (10%–25% of serum levels) are achieved in cerebrospinal fluid, bile, feces, and human milk. The serum half-life is 1 to 1.5 hours, with rapid renal excretion. Plasma concentrations can be higher in patients with hepatic compromise. Side effects, including lassitude, malaise, headache, and dizziness, are common but are mild and transient. More uncommonly, sedation, fever, pruritus, rash, sweating, and severe abdominal discomfort occur.

No specific data on the use of praziquantel in children younger than 4 years of age are available, but no age-specific problems have been reported. Nursing mothers must stop breastfeeding during and for 72 hours after completion of treatment. Tablets must be swallowed whole.

Niclosamide.

Niclosamide is a highly effective, single-dose treatment for the adult stages of *T. saginata, T. solium,* and *D. latum* tapeworm infections.[93] Its production has been discontinued in the United States.

This agent kills the scolex and proximal segments of cestodes on contact by uncoupling oxidative phosphorylation. Because niclosamide causes degeneration of proglottids, a laxative purge 1 to 2 hours after treatment is recommended to reduce the theoretical risk of cysticercosis from release of eggs. Treatment can be repeated in a few days if it is not effective. Mild nausea and abdominal pain are the only reported side effects of this negligibly absorbed compound.

Other Anthelmintic Drugs.

Because *F. hepatica* infection may not respond to praziquantel, a single dose of triclabendazole is regarded by the WHO as the drug of choice for this disorder.[94–96] The drug is available through the CDC.

An older drug for *F. hepatica,* bithionol, can be obtained from the CDC. Bithionol also is an alternative drug for the treatment of *P. westermani* (i.e., lung fluke). Side effects include photosensitivity reactions, urticaria, and gastrointestinal complaints (e.g., vomiting, diarrhea, abdominal pain). Production of bithionol ceased more than 30 years ago, but current stocks retain potency.

Oxamniquine and metrifonate are effective, well-tolerated antischistosomal drugs that most frequently are used in the developing world. Piperazine citrate, piperazine adipate, and piperazine hexahydrate are inexpensive and quite effective treatments for ascariasis or enterobiasis, but because of potential toxicity and the need for prolonged treatment, they should not be used when other agents are available.[97] Pyrvinium pamoate, used in some places for enterobiasis, is no longer available commercially in the United States.

Appendix 296.1 Drugs for Parasitic Infections

Disease	Drug	Adult Dosage	Pediatric Dosage
African trypanosomiasis (African sleeping sickness)			
Trypanosoma brucei rhodesiense, hemolymphatic stage	Suramin[1]	1 g, IV, on days 1, 3, 5, 14, and 21[2]	20 mg/kg (max 1 g), IV, on days 1, 3, 5, 14, and 21[3]
T brucei rhodesiense,	Melarsoprol[4]	2–3.6 mg/kg/day	2–3.6 mg/kg/day

CNS involvement		(max 200 mg), IV, × 3 days[5]	(max 200 mg), IV, × 3 days[5]
		After 7 days, 3.6 mg/kg/day × 3 days	After 7 days, 3.6 mg/kg/day × 3 days
		Give a 3rd series of 3.6 mg/kg/day after 7 days	Give a 3rd series of 3.6 mg/kg/day after 7 days
T brucei gambiense, hemolymphatic stage	Pentamidine[6]	4 mg/kg/day, IV or IM, × 7–10 days	4 mg/kg/day, IV or IM, × 7–10 days
T brucei gambiense, CNS involvement	Eflornithine[7]	400 mg/kg/day, IV, in 4 doses × 14 days	400 mg/kg/day, IV, in 4 doses × 14 days
American trypanosomiasis (Chagas disease; *Trypanosoma cruzi* infection)	Benznidazole[8]	<12 y	5–7.5 mg/kg/day, orally, in 2 divided doses for 60 days
		12 y or older	5–7 mg/kg/day, orally, in 2 divided doses for 60 days
	OR		
	Nifurtimox[8]	1–10 y	15–20 mg/kg/day, orally, in 3 or 4 divided doses for 90 days
		11–16 y	12.5–15 mg/kg/day, orally, in 3 or 4 divided doses for 90 days
		17 y or older	8–10 mg/kg/day, orally, in 3 or 4 divided doses for 90–120 days
Ascariasis (*Ascaris lumbricoides;* intestinal roundworm)	Albendazole[9]	400 mg, orally, once	
	OR		
	Mebendazole[10]	100 mg, orally, twice daily for 3 days, or 500 mg, orally, once	
	OR		
	Ivermectin [11]	150–200 µg/kg, orally, once	
Babesiosis[12]	Atovaquone	750 mg orally twice a day	40 mg/kg/day, orally, in 2 doses (max 750 mg/dose)
	PLUS		
	Azithromycin	On the first day, give a total dose in the range of 500–1000 mg, orally; on subsequent days, give a total daily dose in the range of 250–1000 mg	10 mg/kg (max 500 mg/dose), orally, on day 1, then 5 mg/kg/day (max 250 mg/dose), orally, on subsequent days
	OR		
	Clindamycin	600 mg, orally, 3	20–40 mg/kg/day

		times a day, **or** 300–600 mg, IV, 4 times a day	(max 600 mg/dose), orally, in 3 doses
	PLUS		
	Quinine	650 mg, orally, 3 times a day	30 mg/kg/day, orally, in 3 doses (max 650 mg/dose)
Balantidiasis *(Balantidium coli)*	Tetracycline	500 mg, orally, 4 times daily for 10 days	Age ≥8 y, 40 mg/kg/day (max 2 g), orally, in 4 doses for 10 days
	OR		
	Metronidazole	500–750 mg, orally, 3 times daily for 5 days	35–50 mg/kg/day, orally, in 3 doses for 5 days
	OR		
	Iodoquinol	650 mg, orally, 3 times daily for 20 days	30–40 mg/kg/day (max 2 g), orally, in 3 doses for 20 days
	OR		
	Nitazoxanide	500 mg, orally, twice daily for 3 days	Age 4–11 y: 200 mg, orally, twice daily for 3 days
			Age 1–3 y: 100 mg, orally, twice daily for 3 days
Baylisascariasis (raccoon roundworm infection)	Albendazole[9]	25–50 mg/kg/day, orally, for 10–20 days[13]	
Blastocystis hominis infection[14]	Metronidazole	750 mg, orally, 3 times daily for 10 days	35–50 mg/kg/day, orally, in 3 doses for 10 days
	OR		
	Trimethoprim (TMP)/ sulfamethoxazole (SMX)	160 mg TMP, 800 mg SMX twice daily for 7 days	Age >2 mo: 8 mg TMP/kg and 40 mg/kg SMX per day in 2 divided doses for 7 days
	OR		
	Nitazoxanide	500 mg, orally, twice daily for 3 days	Age 4–11 y: 200 mg, orally, twice daily for 3 days
			Age 1–3 y: 100 mg, orally, twice daily for 3 days
Capillariasis	Mebendazole[10]	200 mg, orally, twice a day for 20 days	
	OR		
	Albendazole[9]	400 mg, orally, once a day for 10 days	
Chilomastix mesnili infection	No treatment is necessary; this protozoan is harmless		
Clonorchiasis	Praziquantel	75 mg/kg/day, orally, 3 doses per day for 2 days	
	OR		
	Albendazole[9]	10 mg/kg/day for 7 days	

Cutaneous larva migrans (zoonotic hookworm)	Albendazole[9]	400 mg/day, orally, once a day for 3 to 7 days	Age >2 y: 400 mg/day, orally, for 3 days
	OR		
	Ivermectin	200 µg/kg, orally, as a single dose	Weight >15 kg: 200 µg/kg, orally, as a single dose
Cyclosporiasis	TMP/SMX	160 mg TMP/800 mg SMX, orally, 2 times/day × 7–10 days	8–10 mg TMP/kg/day, orally, divided 2 times/day for 7–10 days
Cystoisosporiasis (*Cystoisospora* infection; formerly isosporiasis)	TMP/SMX	160 mg TMP/800 mg SMX, orally, 2 times/day × 7–10 days	8–10 mg TMP/kg/day, orally, divided 2 times/day for 7–10 days
	OR		
	Ciprofloxacin (second-line alternate)	500 mg, orally, 2 times/day × 7 days	—
Dientamoeba fragilis infection	Iodoquinol	650 mg, orally, 3 times/day for 20 days	30–40 mg/kg/day (max 2 g), orally, divided 3 times/day × 20 days
	OR		
	Paromomycin	25–35 mg/kg/day, orally, divided 3 times/day for 7 days	
	OR		
	Metronidazole	500–750 mg, orally, 3 times/day for 10 days	35–50 mg/kg/day, orally divided 3 times/day × 10 days
Diplryllobothrium infection	Praziquantel[15]	5–10 mg/kg, orally, in a single dose	
	OR		
	Niclosamide[16]	2 g, orally, once	50 mg/kg (max 2 g), orally, once
Dipylidium caninum infection (dog or cat flea tapeworm)	Praziquantel[15]	5–10 mg/kg, orally, in a single dose	
	OR		
	Niclosamide	2 g, orally, once	50 mg/kg, (max 2 g, orally, once)
Echinococcosis[17]	Albendazole[9]	400 mg, orally, twice a day for 1–6 mo	10–15 mg/kg/day (max 800 mg), orally, in 2 doses for 1–6 mo
Endolimax nana infection	No treatment is necessary; this protozoan is harmless		
Entamoeba coli infection	No treatment is necessary; this protozoan is harmless		
Entamoeba dispar infection	No treatment is necessary; this protozoan is harmless		
Entamoeba hartmanni infection	No treatment is necessary; this protozoan is harmless		
Entamoeba polecki	No treatment is necessary; this protozoan is harmless		
Enterobiasis (pinworm)	Mebendazole[10]	100 mg, orally, once; repeat in 2 wk	
	OR		
	Pyrantel pamoate	11 mg/kg base, orally, once (max 1 g);	

		repeat in 2 wk	
	OR		
	Albendazole[9]	For children 20 kg or greater: 400 mg PO once; repeat in 2 wk	
		For children <20 kg: 200 mg PO once; repeat in 2 wk	
Fascioliasis *(Fasciola hepatica;* sheep liver fluke)	Triclabendazole[18]	10 mg/kg, orally, once or twice	
	OR		
	Nitazoxanide	500 mg, orally, 2 times/day × 7 days	Age 1–3 y: 100 mg, orally, 2 times/day × 7 days
			Age 4–11 y: 200 mg, orally, 2 times/day × 7 days
			Age ≥12 y: 500 mg, orally, 2 times/day × 7 days
Fasciolopsiasis	Praziquantel[15]	75 mg/kg/day, orally, in 3 divided doses for 1 day	
Gnathostomiasis (cutaneous)	Albendazole[9]	400 mg, orally, 2 times/day × 21 days	
	OR		
	Ivermectin	200 µg, orally, once daily × 2 days	
Heterophyiasis	Praziquantel[15]	75 mg/kg/day, divided 3 times/day × 1 day, orally	
Hymenolepiasis *(Hymenolepis nana;* dwarf tapeworm)	Praziquantel[15]	25 mg/kg in a single-dose therapy, orally	
	OR		
	Niclosamide[16]	2 g in a single dose for 7 days, orally	Weight 11–34 kg: 1 g in a single dose on day 1, then 500 mg per day, orally, for 6 days
			Weight >34 kg: 1.5 g in a single dose on day 1, then 1 g per day, orally, for 6 days
	OR		
	Nitazoxanide	500 mg, orally, 2 times/day × 3 days	Age 1–3 y: 100 mg, orally, 2 times/day × 3 days
			Age 4–11 y: 200 mg, orally, 2 times/day × 3 days
			Age ≥12 y: 500 mg, orally, 2 times/day × 3 days
Hookworm (Human; *Ancylostoma duodenale, Necator americanus)*	Albendazole[9]	400 mg, orally, once	
	OR		
	Mebendazole[10]	100 mg, orally, twice a day for 3 days, or 500 mg, orally, once	
	OR		
	Pyrantel pamoate	11 mg/kg (up to a maximum of 1 g), orally, daily for 3 days	
Iodamoeba buetschlii Infection	No treatment is necessary; this protozoan is harmless		

Leishmaniasis[19]			
Visceral (Kala-azar)	Liposomal amphotericin B	3 mg/kg/day, IV, on days 1–5, 14, and 21	
	OR		
	Sodium stibogluconate	20 mg pentavalent antimony (Sb)/kg/day, IV or IM, × 28 days	
	OR		
	Miltefosine	30–44 kg: 50 mg, twice daily, for 28 consecutive days	
		≥ 45 kg: 50 mg, 3 times daily, for 28 consecutive days	
	OR		
	Amphotericin B deoxycholate	1 mg/kg, IV, daily × 15–20 days or every second day for up to 8 wk (total usually 15–20 mg/kg)	
Cutaneous	Sodium stibogluconate	20 mg Sb/kg/day, IV or IM, × 20 days	
	OR		
	Miltefosine	30–44 kg: 50 mg, twice daily, for 28 consecutive days	
		≥45 kg: 50 mg, 3 times daily, for 28 consecutive days	
Mucosal	Sodium stibogluconate	20 mg Sb/kg/day, IV or IM, × 28 days	
	OR		
	Amphotericin B	0.5–1 mg/kg, IV, daily × 15–20 days or every second day for up to 8 wk	
	OR		
	Miltefosine	30–44 kg: 50 mg, twice daily, for 28 consecutive days	
		≥45 kg: 50 mg, 3 times daily, for 28 consecutive days	
Lice infestation *(Pediculus humanus, P capitis, Phthirus pubis)*[20]	Pyrethrins with piperonyl butoxide[21]	Topically, twice, at least 7 days apart	Topically, twice at least 7 days apart
	OR		
	0.5% Ivermectin lotion[22]	Topically, once	Topically, once
	OR		
	0.9% Spinosad suspension[23]	Topically, twice, at least 7 days apart	Topically, twice, at least 7 days apart
	OR		
	1% Permethrin[21]	Topically, twice, at least 7 days apart	Topically, twice, at least 7 days apart
	OR		
	5% Benzyl alcohollotion[24]	Topically, twice, at least 7 days apart	Topically, twice, at least 7 days apart
	OR		
	0.5% Malathion[25]	Topically, twice, at least 7 days apart	Topically, twice, at least 7 days apart
	OR		
	Ivermectin[26]	200 or 400 µg/kg, orally	≥15 kg: 200 or 400 µg/kg, orally
Loiasis *(Loa loa)*	*Indication:*		
	Symptomatic loiasis with microfilariae of L loa/mL <8000		
	Diethylcarbamazine (DEC)[27]	8–10 mg/kg, orally, in 3 divided doses	

		daily for 21 days	
	Indication:		
	Symptomatic loiasis, with microfilariae of L loa/mL <8000 and foiled 2 rounds DEC		
	OR		
	Symptomatic loiasis, with microfilariae of L loa/mL ≥8000 to reduce level to <8000 prior to treatment with DEC		
	Albendazole[9]	200 mg, orally, twice daily for 21 days	
Lymphatic filariasis (elephantiasis; *Wuchereria bancrofti, Brugia malayi, Brugia timori)*	Diethylcarbamazine (DEC)[27]	Treatment of lymphatic filariasis: Adults and children >18 mo: 6 mg/kg/day, orally, divided in 3 doses for 12 consecutive days OR 6 mg/kg/day as a single oral dose Treatment of tropical pulmonary eosinophilia (TPE): Adults and children >18 mo: 6 mg/kg/day, orally, divided in 3 doses for 14–21 days	
Malaria *(Plasmodium* species)	Region infection acquired		
Uncomplicated malaria *P folcipanan* or species not identified	Chloroquine-resistant or unknown resistance[28,29] (All malarious regions except those specified as chloroquine-sensitive listed below.)		
If "species not identified" subsequently diagnoses as *P vivax* or *P ovale,* see below re: treatment with primaquine	Atovaquone-proguanil[30]	1000 mg atovaquone/400 mg proguanil, orally, once daily × 3 days	Weight 5–8 kg: 2 pediatric tablets, orally, once daily × 3 days
			Weight 9–10 kg: 3 pediatric tablets, orally, once daily × 3 days
			Weight 11–20 kg: 1 adult tablets, orally, once daily × 3 days
			Weight 21–30 kg: 2 adult tablets, orally, once daily × 3 days
			31–40 kg: 3 adult tablets, orally, once daily × 3 days
			>40 kg: 4 adult tablets, orally, once daily × 3 days
	OR		
	Artemether-lumefantrine[30]	A 3-day treatment schedule with a total of 6 oral doses is recommended for both adult and pediatric patients based on weight. The patient should receive the initial dose, followed by the second dose 8 h later, then 1 dose, orally, 2 times/day, for the following 2 days.	

	1 tablet = 20 mg artemether and 120 mg lumefantrine	Weight 5 to <15 kg: 1 tablet per dose Weight 15 to <25 kg: 2 tablets per dose Weight 25 to <35 kg: 3 tablets per dose Weight ≥35 kg: 4 tablets per dose	
	OR		
	Quinine sulfate[31,32] plus one of the following: Doxycycline,[33] Tetracycline,[33] or Clindamycin	Quinine sulfate: 542 mg base (=650 mg salt),[4] orally, 3 times/ day × 3 or 7 days[5]	Quinine sulfate: 8.3 mg base/kg (=10 mg salt/kg), orally, 3 times/day × 3 or 7 days
		Doxycycline: 100 mg, orally, 2 times/day × 7 days	Doxycycline: 2.2 mg/kg, orally, every 12 h × 7 days
		Tetracycline: 250 mg, orally, 4 times/day × 7 days	Tetracycline: 25 mg/kg/day, orally, divided 4 times/day × 7 days
		Clindamycin: 20 mg base/kg/day, orally, divided 3 times/day × 7 days	Clindamycin: 20 mg base/kg/day, orally, divided 3 times/day × 7 days
	OR	Mefloquine[34] 684 mg base (=750 mg salt), orally, as initial dose, followed by 456 mg base (=500 mg salt), orally, given 6–12 h after initial dose Total dose = 1250 mg salt	13.7 mg base/kg (=15 mg salt/kg), orally, as initial dose, followed by 9.1 mg base/kg (=10 mg salt/ kg), orally, given 6–12 h after initial dose Total dose = 25 mg salt/kg
Uncomplicated malaria	Chloroquine-sensitive		
P falciparum or species not identified	(Central America west of Panama Canal; Haiti; the Dominican Republic; and most of the Middle East)		
	Chloroquine phosphate[35]	600 mg base (=1000 mg salt), orally, immediately, followed by 300 mg base (=500 mg salt), orally, at 6, 24, and 48 h Total dose: 1500 mg base (=2500 mg salt)	10 mg base/kg, orally, immediately, followed by 5 mg base/kg, orally, at 6, 24, and 48 h Total dose: 25 mg base/kg
	OR		
	Hydroxychloroquine	620 mg base (=800 mg salt), orally, immediately, followed by 310 mg base (=400 mg salt), orally, at 6, 24, and 48 h	10 mg base/kg, orally, immediately, followed by 5 mg base/kg, orally, at 6, 24, and 48 h Total dose: 25 mg

		Total dose: 1550 mg base (=2000 mg salt)	base/kg
	All regions		
	Chloroquine phosphate[35]	600 mg base (=1000 mg salt), orally, immediately, followed by 300 mg base (=500 mg salt), orally, at 6, 24, and 48 h	10 mg base/kg, orally, immediately, followed by 5 mg base/kg, orally, at 6, 24, and 48 hours Total dose: 25 mg base/kg
Uncomplicated malaria *P malariae or P knowlesi*		Total dose: 1500 mg base (=2500 mg salt)	
	OR		
	Hydroxychloroquine	620 mg base (=800 mg salt), orally, immediately, followed by 310 mg base (=400 mg salt), orally, at 6, 24, and 48 h Total dose: 1550 mg base (=2000 mg salt)	10 mg base/kg, orally, immediately, followed by 5 mg base/kg, orally, at 6, 24, and 48 h Total dose: 25 mg base/kg
	All regions		
	Note: for suspected chloroquine-resistant *P vivax,* see row below		
	Chloroquine phosphate[35]	600 mg base (=1000 mg salt), orally, immediately, followed by 300 mg base (=500 mg salt), orally, at 6, 24, and 48 h Total dose: 1500 mg base (=2500 mg salt)	10 mg base/kg, orally, immediately, followed by 5 mg base/kg, orally, at 6, 24, and 48 h Total dose: 25 mg base/kg
	PLUS		
Uncomplicated malaria *P vivax* or *P ovale*	Primaquine phosphate[36]	30 mg base, orally, once daily × 14 days	0.5 mg base/kg, orally, once daily × 14 days
	OR		
	Hydroxychloroquine	620 mg base (=800 mg salt), orally, immediately, followed by 310 mg base (=400 mg salt), orally, at 6, 24, and 48 h Total dose: 1550 mg base (=2000 mg salt)	10 mg base/kg, orally, immediately, followed by 5 mg base/kg, orally, at 6, 24, and 48 h Total dose: 25 mg base/kg
	PLUS		
	Primaquine phosphate[36]	30 mg base, orally, once daily × 14	0.5 mg base/kg, orally, once daily

		days	× 14 days
Uncomplicated malaria	Chloroquine-resistant[37] (Papua New Guinea and Indonesia)		
P vivax	Quinine sulfate plus either Doxycycline or Tetracycline plus Primaquine phosphate[36]	Quinine sulfate: 542 mg base (=650 mg salt),[4] orally, 3 times/ day × 3 or 7 days[32]	Quinine sulfate: 8.3 mg base/kg (=10 mg salt/kg), orally, 3 times/ day × 3 or 7 days[32]
		Doxycycline: 100 mg, orally, 2 times/day × 7 days	Doxycycline: 2.2 mg/kg, orally, every 12 h × 7 days
		Tetracycline: 250 mg, orally, 4 times/day × 7 days	Tetracycline: 25 mg/kg/day, orally, divided 4 times/day × 7 days
		Primaquine phosphate: 30 mg base, orally, once daily × 14 days	Primaquine Phosphate: 0.5 mg base/kg, orally, once daily × 14 days
	OR		
	Atovaquone-proguanil plus Primaquine phosphate[36]	Atovaquone-proguanil: 1000 mg atovaquone/400 mg proguanil, orally, once daily × 3 days	Atovaquone-proguanil: 5–8 kg: 2 pediatric tablets, orally, once daily × 3 days 9–10 kg: 3 pediatric tablets, orally, once daily × 3 days 11–20 kg: 1adult tablet, orally, once daily × 3 days 21–30 kg: 2 adult tablets, orally, once daily × 3 days
		Primaquine phosphate: 30 mg base, orally, once daily × 14 days	31–40 kg: 3 adult tablets, orally, once daily × 3 days >40 kg: 4 adult tablets, orally, once daily × 3 days Primaquine phosphate: 0.5 mg base/kg, orally, once daily × 14 days
	OR		
	Mefloquine plus Primaquine phosphate[36]	Mefloquine: 684 mg base (=750 mg	Mefloquine: 13.7 mg base/kg (=15

		salt), orally, as initial dose, followed by 456 mg base (=500 mg salt), orally, given 6–12 h after initial dose Total dose = 1250 mg salt	mg salt/kg), orally, as initial dose, followed by 9.1 mg base/ kg (=10 mg salt/kg), orally, given 6–12 h after initial dose Total dose = 25 mg salt/kg
		Primaquine phosphate: 30 mg base, orally, once daily × 14 days	Primaquine phosphate: 0.5 mg base/kg, orally, once daily × 14 days
Uncomplicated malaria: alternatives for pregnant women[38,39,40]	Chloroquine-sensitive		
	(see uncomplicated malaria sections above for chloroquine-sensitive species by region)		
	Chloroquine phosphate[35]	600 mg base (=1000 mg salt), orally, immediately, followed by 300 mg base (=500 mg salt), orally, at 6, 24, and 48 h Total dose: 1500 mg base (=2500 mg salt)	Not applicable
	OR		
	Hydroxychloroquine	620 mg base (=800 mg salt), orally, immediately, followed by 310 mg base (=400 mg salt), orally, at 6, 24, and 48 h Total dose: 1550 mg base (=2000 mg salt)	Not applicable
	Chloroquine-resistant		
	(see sections above for regions with chloroquine resistant *P falciparum and P vivax)*		
	Quinine sulfate plus Clindamycin	Quinine sulfate: 542 mg base (=650 mg salt),[4] orally, 3 times/ day × 3 or 7 days[5]	Not applicable
		Clindamycin: 20 mg base/kg/day, orally, divided 3 times/day × 7 days	
	OR		
	Mefloquine	684 mg base (=750 mg salt), orally, as initial dose, followed by 456 mg base (=500 mg	Not applicable

		salt), orally, given 6–12 h after initial dose Total dose =1250 mg salt		
Severe malaria[41,42,43]	All regions			
	Quinidine gluconate[31] plus one of the following: Doxycycline, Tetracycline, or Clindamycin	Quinidine gluconate: 6.25 mg base/kg (=10 mg salt/kg) loading dose, IV over 1–2 h, then 0.0125 mg base/kg/min (=0.02 mg salt/kg/min) continuous infusion for at least 24 h. An alternative regimen is 15 mg base/kg (=24 mg salt/ kg) loading dose, IV infused over 4 h, followed by 7.5 mg base/kg (=12 mg salt/kg) infused over 4 h every 8 h, starting 8 h after the loading dose (see package insert). Once parasite density <1% and patient can take oral medication, complete treatment with oral quinine, dose as above. Quinidine/quinine course = 7 days in Southeast Asia; = 3 days in Africa or South America.	Quinidine gluconate: Same mg/kg dosing and recommendations as for adults. Doxycycline: 2.2 mg/kg, orally, every 12 h × 7 days. If patient not able to take oral medication, may give IV. For children <45 kg, give 2.2 mg/kg, IV, every 12 h and then switch to oral doxycycline (dose as above) as soon as patient can take oral medication. For children >45 kg, use same dosing as for adults. For IV use, avoid rapid administration. Treatment course = 7 days. Tetracycline: 25 mg/kg/day, orally, divided 4 times/day × 7 days	
		Doxycycline: 100 mg, orally, 2 times/day × 7 days If patient not able to take oral medication, give 100 mg, IV, every 12 h and then switch to oral doxycycline (as above) as soon as patient can take oral medication. For IV use, avoid rapid	Clindamycin: 20 mg base/kg/day, orally, divided 3 times/day × 7 days. If patient not able to take oral medication, give 10 mg base/kg loading dose, IV, followed by 5 mg base/kg, IV, every 8 h. Switch to oral clindamycin (oral dose as above) as	

		administration. Treatment course = 7 days.	soon as patient can take oral medication. For IV use, avoid rapid administration. Treatment course = 7 days.
		Tetracycline: 250 mg, orally, 4 times/day × 7 days	*Investigational new drug (contact CDC for information)*
		Clindamycin: 20 mg base/kg/day, orally, divided 3 times/day × 7 days. If patient not able to take oral medication, give 10 mg base/kg loading dose, IV, followed by 5 mg base/kg, IV, every 8 h. Switch to oral clindamycin (oral dose as above) as soon as patient can take oral medication. For IV use, avoid rapid administration. Treatment course = 7 days.	Artesunate followed by one of the following: atovaquone-proguanil, clindamycin, or mefloquine
		Investigational new drug (contact CDC for information)	
		Artesunate followed by one of the following: atovaquone-proguanil, doxycycline (clindamycin in pregnant women), or mefloquine	
Neurocysticercosis[44]	Albendazole[9]	400 mg, orally, 2 times/day × 15 days; can be repeated as necessary	15 mg/kg/day (max 800 mg), orally, in divided 2 times/day × 15 days; can be repeated as necessary
	OR		
	Praziquantel[15]	100 mg/kg/day, orally, in 3 divided doses × 1 day, then 50 mg/kg/day in 3 divided doses × 29 days	
Onchocerciasis (*Onchocerca volvulus;* River	Ivermectin	150 µg/kg, orally, in 1 dose every 6 mo until asymptomatic	
	OR		

Blindness)[45]	Doxycycline[46]	200 mg, orally, daily for 6 wk	
Opisthorchis Infection (Southeast Asian liver fluke)	Praziquantel[15]	75 mg/kg/day, orally, divided 3 times/day for 2 days	
	OR		
	Albendazole[9]	10 mg/kg/day, orally, for 7 days	
Paragonimiasis	Praziquantel[15]	75 mg/kg/day, orally, divided 3 times/day for 2 days	
	OR		
	Triclabendazole[18]	10 mg/kg, orally, once or twice	
Scabies (Mite Infestation)	Permethrin cream 5%	Topically, twice, at least 7 days apart	
	OR		
	Crotamiton lotion 10% and Crotamiton cream 10%	Topically, overnight, on days 1, 2, 3, and 8	
	OR		
	Ivermectin	200 µg/kg, orally, twice, at least 7 days apart	
Schistosomiasis (Bilharzia)	*Schistosoma mansoni, S haematobium, S intercalatum*		
	Praziquantel[15]	40 mg/kg/day, orally, divided 2 times/day for 1 day	
	S japonicum, S mekongi		
	Praziquantel[15]	60 mg/kg/day, orally, divided 3 times/day for 1 day	
Strongyloidiasis	Ivermectin	200 µg/kg, orally, daily for 1–2 days; for patients unable to take ivermectin orally, a parenteral formulation is available commercially for veterinary use and used under a single patient investigational new drug application on request to FDA	
	OR		
	Albendazole[9]	400 mg, orally, divided 2 times/day for 7 days	
Taeniasis [*Taenia saginata* (beef tapeworm), *Taenia solium* (pork tapeworm), and *Taenia asiatica* (Asian tapeworm)]	Praziquantel[15]	5–10 mg/kg, orally, once	
	OR		
	Niclosamide[16]	2 g, orally, once	50 mg/kg, orally, once
Toxocariasis (Ocular Larva Migrans, Visceral Larva Migrans)	Albendazole[9]	400 mg, orally, 2 times/day × 5 days	
	OR		
	Mebendazole[10]	100–200 mg, orally, 2 times/day × 5 days	
Toxoplasmosis CNS disease (*Toxoplasma gondii)*[47]	Pyrimethamine[48]	200 mg, orally, once, then 50–75 mg/day, orally × 3–6 wk	2 mg/kg/day, orally, × 2 days, then 1 mg/kg/day (max 25 mg/day) × 3–6 wk
	PLUS		
	Sulfadiazine	1.5 g, orally, 4 times/day × 3–6 wk	100–200 mg/kg/day, 6 h × 3–6 wk
	OR		
	Pyrimethamine[48]	200 mg, orally, once, then 50–75 mg/day, orally, × 3–6 wk	2 mg/kg/day, orally, × 2 days, then 1 mg/kg/day (max 25 mg/day) ×

			3–6 wk
	PLUS		
	Clindamycin	1.8–2.4 g/day, IV or orally, divided 3 or 4 times/day × 3–6 wk	5–7.5 mg/kg/dose (max 600 mg/ dose), orally, divided 3 or 4 times/day × 3–6 wk
	OR		
	Pyrimethamine[48]	200 mg, orally, once, then 50–75 mg/day, orally, × 3–6 wk	2 mg/kg/day, orally, × 2 days, then 1 mg/kg/day (max 25 mg/day) × 3–6 wk
	PLUS		
	Atovaquone	1500 mg, orally, 2 times/day	See footnote 47.
	OR		
	Trimethoprim/Sulfamethoxazole	15–20 mg/kg TMP and 75–100 mg/kg SMX per day divided 3 or 4 times/day × 3–6 wk	15–20 mg/kg TMP and 75–100 mg/kg SMX per day divided 3 or 4 times/day × 3–6 wk
Toxoplasmosis in pregnancy and neonates *(Toxoplasma gondii)*	See footnote 49.		
Trichinellosis (trichinosis; *Trichinella species)*	Albendazole[9]	400 mg, orally, twice a day for 8–14 days	
	OR		
	Mebendazole[10]	200–400 mg, orally, 3 times a day for 3 days, then 400–500 mg, orally, 3 times a day for 10 days	
Trichuriasis (whipworm infection; *Trichuris trichiura)*	Albendazole[9]	400 mg, orally, for 3 days	
	OR		
	Mebendazole[10]	100 mg, orally, twice a day for 3 days	
	OR		
	Ivermectin	200 µg/kg/day, orally, for 3 days	

[1] Pentamidine is also effective against *T b rhodesiense* in the hemolymphatic stage, but suramin may have somewhat higher efficacy Suramin is not approved by the FDA but is available through the CDC Drug Service.

[2] A suramin test dose of 100 mg should be given prior to the first dose and the patient should be monitored for hemodynamic stability.

[3] A suramin test dose of 2 mg/kg (max 100 mg) should be given prior to the first dose and the patient should be monitored for hemodynamic stability.

[4] Corticosteroids have been used to prevent melarsoprol encephalopathy. Melarsoprol is not approved by the FDA but is available through the CDC Drug Service.

[5] The dose of melarsoprol is progressively increased during the first series.

[6] Suramin is also effective against *T b gambiense* in the hemolymphatic stage but should be used only in patients in whom onchocerciasis has been excluded. Suramin

is not approved by the FDA but is available through the CDC Drug Service.

[7] Eflornithine (400 mg/kg/day, IV, in 2 doses × 7 days) given in combination with oral nifurtimox (15 mg/kg/day, in 3 divided doses × 10 days) is also highly effective against *T b gambiense* with CNS involvement; eflornithine is not approved by the FDA but is available through the CDC Drug Service. Nifurtimox is not FDA-approved, nor is this use covered by CDC's Investigational New Drug (IND) protocol for nifurtimox, which solely covers treatment of Chagas disease; permission for other uses would need to be obtained.

[8] The 2 drugs used to treat infection with *Trypanosoma cruzi* are benznidazole and nifurtimox. In the United States, these drugs are not FDA approved and are available only from CDC under investigational protocols. For both drugs, adverse effects are fairly common and tend to be more frequent and more severe with increasing age. Questions regarding treatment should be directed to Parasitic Diseases Public Inquiries (404-718-4745; e-mail **chagas@cdc.gov**).

[9] The safety of albendazole in children younger than 6 years is not certain. Studies of the use of albendazole in children as young as 1 year suggest that its use is safe.

[10] The safety of mebendazole in children has not been established. There are limited data in children 2 years and younger.

[11] Safety of ivermectin for treating children who weigh less than 15 kg has not been established.

[12] Usually treat for at least 7 to 10 days. The combination of clindamycin plus quinine is the standard of care for babesiosis patients who are severely ill.

[13] In cases in which suspicion of exposure is high, immediate treatment with albendazole (25–50 mg/kg per day by mouth for 10–20 days) may be appropriate. Treatment is successful when administered soon after exposure to abort the migration of larvae. Treatment should be initiated as soon as possible after ingestion of infectious material, ideally within 3 days. For clinical baylisascariasis, treatment with albendazole with concurrent corticosteroids to help reduce the inflammatory reaction is indicated to attempt to control the disease.

[14] The clinical significance of *Blastocystis* species is controversial.

[15] Praziquantel is not approved for treatment of children younger than 4 years, but this drug has been used successfully to treat cases of *D caninum* infection in children as young as 6 months.

[16] Niclosamide is unavailable in the United States.

[17] Treatment of cystic echinococcosis depends on the world Health Organization classification of the cysts. Albendazole is not appropriate for all forms of the infection.

[18] Triclabendazole is not approved by the FDA but is available through the CDC Drug Service. It requires an individual IND from the FDA for administration.

[19] Sodium stibogluconate is not approved by the FDA but is available through the CDC Drug Service. Only selected treatments and regimens are provided. Expert consultation about these and other potential treatment options for leishmaniasis is encouraged. For some cases of cutaneous leishmaniasis, no therapy may be needed or local (vs systemic) therapy may suffice or other systemic treatments may be considered. Miltefosine (IMPAVIDO) was approved in March 2014 by the FDA for

treatment of visceral leishmaniasis attributable to *L donovani,* mucosal leishmaniasis attributable to *L braziliensis,* and cutaneous leishmaniasis attributable to *L braziliensis, L guyanensis,* and *L panamensis* (ie, some new world cutaneous leishmaniasis species, but no old world cutaneous leishmaniasis species) for patients who are at least 12 years of age and at least 30 kg of weight.

[20] Pediculicides should not be used for infestations of the eyelashes. Such infestations are treated with petrolatum ointment applied 2 to 4 times/day for 8 to 10 days. For pubic lice, treat with 1% permethrin, pyrethrins with piperonyl butoxide, or ivermectin.

[21] Permethrin and pyrethrin are pediculicidal; retreatment in 7 to 10 days is needed to eradicate the infestation. Some lice are resistant to pyrethrins and permethrin. Pyrethrins with piperonyl butoxide are recommended for use in children >2 years old; permethrin for children >2 months old.

[22] Ivermectin is not ovicidal, but lice that hatch from treated eggs die within 48 hours after hatching. Recommended for use in children >6 months old.

[23] Spinosad is not ovicidal, but causes neuronal excitation in insects leading to paralysis and death. The formulation also includes benzyl alcohol, which is pediculicidal Two applications 7 days apart are needed. Recommended for children >4 years old.

[24] Benzyl alcohol prevents lice from closing their respiratory spiracles and the lotion vehicle then obstructs their airway causing them to asphyxiate. It is not ovicidal. Two applications at least 7 days apart are needed. Recommended for use in children >6 months old. Resistance, which is a problem with other drugs, is unlikely to develop.

[25] Malathion is both ovicidal and pediculicidal; 2 applications at least 7 days apart are generally necessary to kill all lice and nits. Recommended for children >6 years old.

[26] Ivermectin is pediculicidal, but not ovicidal; more than 1 dose is generally necessary to eradicate the infestation. The number of doses and interval between doses has not been established; animal studies have shown adverse effects on the fetus. In one study of treatment of head lice, 2 doses of ivermectin (400 µg/kg) 7 days apart were more effective than treatment with topical malathion. In one study of treatment of body lice, a regimen of 3 doses of ivermectin (12 mg each) administered at 7-day intervals was effective.

[27] Diethylcarbamazine (DEC) is not approved by the FDA, but is available from the CDC Drug Service through an IND after confirmed positive lab results. DEC is contraindicated in patients who may also have onchocerciasis. Prior to DEC treatment for lymphatic filariasis, onchocerciasis should be excluded in all patients with a consistent exposure history because of the possibility of severe exacerbations of skin and eye involvement (Mazzotti reaction). People coinfected with loiasis and *O volvulus* should not be treated with DEC until the onchocerciasis is treated; their onchocerciasis should not be treated with ivermectin if it is unsafe to treat their loiasis.

[28] If a person develops malaria despite taking chemoprophylaxis, that particular medicine should not be used as a part of their treatment regimen. Use one of the other options instead.

[29] There are 4 options (A, B, C, or D) available for treatment of uncomplicated malaria

caused by chloroquine-resistant *P falciparum.* Options A, B, and C are equally recommended. Because of a higher rate of severe neuropsychiatric reactions seen at treatment doses, option D (mefloquine) is not recommended unless the other options cannot be used. For option C, because there are more data on the efficacy of quinine in combination with doxycycline or tetracycline, these treatment combinations are generally preferred to quinine in combination with clindamycin.

[30] Atovaquone-proguanil or artemether-lumefantrine should be taken with food or whole milk. If patient vomits within 30 minutes of taking a dose, the dose should be repeated.

[31] The US-manufactured quinine sulfate capsule is in a 324-mg dosage; therefore, 2 capsules should be sufficient for adult dosing. Pediatric dosing may be difficult because of unavailability of noncapsule forms of quinine.

[32] For infections acquired in Southeast Asia, quinine treatment should continue for 7 days. For infections acquired elsewhere, quinine treatment should continue for 3 days.

[33] Doxycycline and tetracycline are not indicated for use in children younger than 8 years. For children younger than 8 years with chloroquine-resistant *P falciparum,* atovaquone-proguanil and artemether-lumefantrine are recommended treatment options; mefloquine can be considered if no other options are available. For children younger than 3 years with chloroquine-resistant *P vivax,* mefloquine is the recommended treatment. If it is not available or is not being tolerated and if the treatment benefits outweigh the risks, atovaquone-proguanil or artemether-lumefantrine should be used instead.

[34] Treatment with mefloquine is not recommended in people who have acquired infections from Southeast Asia because of drug resistance.

[35] When treating chloroquine-sensitive infections, chloroquine and hydroxychloroquine are recommended options. However, regimens used to treat chloroquine-resistant infections may also be used if available, more convenient, or preferred.

[36] Primaquine is used to eradicate any hypnozoites that may remain dormant in the liver and, thus, prevent relapses in *P vivax* and *P ovale* infections. Because primaquine can cause hemolytic anemia in glucose-6-phosphate dehydrogenase (G6PD)-deficient people, G6PD screening must occur prior to starting treatment with primaquine. For people with borderline G6PD deficiency or as an alternate to the above regimen, primaquine, 45 mg, orally, once per week for 8 weeks may be given; consultation with an expert in infectious disease and/or tropical medicine is advised if this alternative regimen is considered in G6PD-deficient people. Primaquine must not be used during pregnancy.

[37] There are 3 options (A, B, or C) available for treatment of uncomplicated malaria caused by chloroquine-resistant *P vivax.* High treatment failure rates attributable to chloroquine-resistant *P vivax* have been well documented in Papua New Guinea and Indonesia. Rare case reports of chloroquine-resistant *P vivax* have also been documented in Burma (Myanmar), India, and Central and South America. People acquiring *P vivax* infections outside of Papua New Guinea or Indonesia should be started on chloroquine. If the patient does not respond, the treatment should be changed to a chloroquine-resistant *P vivax* regimen and the CDC should be notified

(Malaria Hotline number listed previously). For treatment of chloroquine-resistant *P vivax* infections, options A, B, and Care equally recommended.

[38]For pregnant women diagnosed with uncomplicated malaria caused by chloroquine-resistant *P falciparum* or chloroquine-resistant *P vivax* infection, treatment with doxycycline or tetracycline is generally not indicated. However, doxycycline or tetracycline may be used in combination with quinine (as recommended for nonpregnant adults) if other treatment options are not available or are not being tolerated, and the benefit is judged to outweigh the risks.

[39]Atovaquone-proguanil and artemether-lumefantrine are generally not recommended for use in pregnant women, particularly in the first trimester, because of lack of sufficient safety data. For pregnant women diagnosed with uncomplicated malaria caused by chloroquine-resistant *P falciparum* infection, atovaquone-proguanil or artemether-lumefantrine may be used if other treatment options are not available or are not being tolerated, and if the potential benefit is judged to outweigh the potential risks.

[40]For *P vivax* and *P ovale* infections, primaquine phosphate for radical treatment of hypnozoites should not be given during pregnancy. Pregnant patients with *P vivax* and *P ovale* infections should be maintained on chloroquine prophylaxis for the duration of their pregnancy. The chemoprophylactic dose of chloroquine phosphate is 300 mg base (=500 mg salt), orally, once per week. After delivery, pregnant patients who do not have G6PD deficiency should be treated with primaquine.

[41]People with a positive blood smear OR history of recent possible exposure and no other recognized pathologic abnormality who have 1 or more of the following clinical criteria (impaired consciousness/coma, severe normocytic anemia, renal failure, pulmonary edema, acute respiratory distress syndrome, circulatory shock, disseminated intravascular coagulation, spontaneous bleeding, acidosis, hemoglobinuria, jaundice, repeated generalized convulsions, and/or parasitemia of >5%) are considered to have manifestations of more severe disease. Severe malaria is most often caused by *P falciparum.*

[42]Patients with a diagnosis of severe malaria should be treated aggressively with parenteral antimalarial therapy. Treatment with IV quinidine should be initiated as soon as possible after the diagnosis has been made. Patients with severe malaria should be given an intravenous loading dose of quinidine unless they have received more than 40 mg/kg of quinine in the preceding 48 hours or if they have received mefloquine within the preceding 12 hours. Consultation with a cardiologist and a physician with experience treating malaria is advised when treating malaria patients with quinidine. During administration of quinidine, blood pressure monitoring (for hypotension) and cardiac monitoring (for widening of the QRS complex and/or lengthening of the QTc interval) should be monitored continuously and blood glucose (for hypoglycemia) should be monitored periodically. Cardiac complications, if severe, may warrant temporary discontinuation of the drug or slowing of the intravenous infusion.

[43]Pregnant women diagnosed with severe malaria should be treated aggressively with parenteral antimalarial therapy.

[44]Albendazole is currently the treatment of choice for neurocysticercosis. Longer courses may be needed for subarachnoid disease. Steroids are almost always required when albendazole or praziquantel is used. Not all forms of

neurocysticercosis should be treated with anthelmintics. Some forms should only be treated with surgery. Some forms require only symptom control.

[45] People coinfected with *O volvulus* and loiasis should not be treated with diethylcarbamazine (DEC) until the onchocerciasis is treated; their onchocerciasis should not be treated with ivermectin if it is unsafe to treat their loiasis. Patients should only be treated with doxycycline if they no longer live in areas with endemic infection unless there is a contraindication for ivermectin.

[46] Doxycycline is not standard therapy, but several studies support its use and safety. Treatment with ivermectin should be given 1 week prior to treatment with doxycycline to provide symptom relief to the patient. If the patient cannot tolerate the dosage of 200 mg, orally, daily of doxycycline, 100 mg, orally, daily is sufficient to sterilize female *Onchocerca organisms.*

[47] For treatment and chronic suppression of toxoplasmosis in human immunodeficiency virus (HIV) infected children, see Guidelines for the Prevention and Treatment of Opportunistic Infections Among HIV-Exposed and HIV-Infected Children, 2013 at **http://aidsinfo.nih.gov/contentfiles/lvguidelines/oi_guidelines_pediatrics.pdf**.

[48] Pius leucovorin, 10–25 mg, with each dose of pyrimethamine.

[49] Women who develop toxoplasmosis during the first trimester of pregnancy should be treated with spiramycin (3–4 g/day). After the first trimester, if there is no documented transmission to the fetus, spiramycin can be continued until term. Spiramycin is not currently available in the United States but can be obtained at no cost from Aventis through an IND from the FDA (301-796-1600, -1400, -0563, or -3763) following confirmation of the diagnosis by a recognized laboratory (ie, Palo Alto Medical Foundation, Toxoplasmosis Laboratory 650-853-4828). If transmission has occurred in utero, therapy with pyrimethamine and sulfadiazine should be started. Pyrimethamine is a potential teratogen and should be used only after the first trimester (Montoya JG, Remington JS. Management of Toxoplasma gondii infection during pregnancy. *Clin Infect Dis.* 2008;47 [4]:554). Congenitally infected newborns should be treated with pyrimethamine every 2 or 3 days and a sulfonamide daily for approximately 1 year (Remington JS, McLeod R, Wilson CB, Desmonts G. Toxoplasmosis. Remington JS, Klein J, Wilson C, Nizet V, Maldonado Y, eds. *Infectious Disease of the Fetus and Newborn Infant.* 7th ed. Philadelphia, PA: Saunders; 2011:918-1041).

CDC, Centers for Disease Control and Prevention; IV, intravenous; CNS, central nervous system; IM, intramuscular; FDA, US Food and Drug Administration.

From American Academy of Pediatrics. Drugs for parasitic infections. In: Kimberlin DW, Brady MT, Jackson MA, Long SS (eds). Red Book: 2015 Report on the Committee on Infectious Diseases, 30th ed. Elk Grove Village, IL, American Academy of Pediatrics, 2015:927–956.

Appendix 296.2 Principal Adverse Effects of Antiparasitic Drugs

Adverse effects of antiparasitic drugs vary with dosage, duration of administration, concomitant therapy, renal and hepatic function, immune competence, and the age of the patient. The principal adverse effects of antiparasitic agents are listed in the following table. The designation of adverse effects as “frequent,” “occasional,” or “rare” is based on published reports and on the experience of Medical Letter consultants.

ALBENDAZOLE *(Albenza)*

Frequent: abdominal pain; increased serum transaminases

Occasional: reversible alopecia; leukopenia

Rare: rash; hepatic toxicity; renal toxicity

AMPHOTERICIN B DEOXYCHOLATE (*Fungizone*, and generics)

Frequent: renal damage; hypokalemia; thrombophlebitis at site of peripheral vein infusion; anorexia; headache; nausea; weight loss; bone marrow suppression with reversible decline in hematocrit; chills, fever, vomiting during infusion, possibly with delirium, hypotension or hypertension, wheezing, and hypoxemia, especially in cardiac or pulmonary disease

Occasional: hypomagnesemia; normocytic, normochromic anemia

Rare: hemorrhagic gastroenteritis; blood dyscrasias; rash; blurred vision; peripheral neuropathy; convulsions; anaphylaxis; arrhythmias; acute liver failure; reversible nephrogenic diabetes insipidus; hearing loss; acute pulmonary edema; spinal cord damage with intrathecal use

AMPHOTERICIN B LIPID FORMULATIONS *(AmBisome, Abelcet, Amphotec)*

Similar to amphotericin B but generally better tolerated. Nephrotoxicity is less common and less severe with the lipid-based formulations.

Acute infusion reactions are worse with Amphotec, less with Abelcet and least with AmBisome. Liver toxicity has been reported.

ARTEMETHER *(Artenam)*

Occasional: neurological toxicity; possible increase in length of coma; increased convulsions; prolongation of QTc interval

ARTEMETHER/LUMEFANTRINE *(Coartem, Riamet)*

Frequent: abdominal pain; anorexia; headache; dizziness; diarrhea; vomiting; nausea; palpitations; arthralgia; myalgia; asthenia; fatigue; pruritus; rash; sleep disorder; cough

Occasional: somnolence; involuntary muscle contractions; paresthesia; hypoesthesia; abnormal gait; ataxia

Rare: hypersensitivity

ARTESUNATE

Occasional: ataxia; slurred speech; neurological toxicity; possible increase in length of coma; increased convulsions; prolongation of QTc interval

ATOVAQUONE (*Mepron, Malarone* [with proguanil])

Frequent: rash; nausea

Occasional: diarrhea; increased aminotransferases; cholestasis

AZITHROMYCIN (*Zithromax*, and generics)

Occasional: nausea; diarrhea; abdominal pain; headache; dizziness; vaginitis

Rare: angioedema; cholestatic jaundice; photosensitivity; reversible dose-related hearing loss; QT prolongation

BENZNIDAZOLE *(Rochagan)*

Frequent: allergic rash; dose-dependent polyneuropathy; GI disturbance; psychic disturbances

BENZYL ALCOHOL *(Ulesfia Lotion)*

Frequent: eye irritation; contact dermatitis

BITHIONOL *(Bitin)*

Frequent: photosensitivity reactions; vomiting; diarrhea; abdominal pain; urticaria

Rare: leukopenia; toxic hepatitis

CHLOROQUINE HCL and **CHLOROQUINE PHOSPHATE** (*Aralen*, and generics)

Occasional: pruritus; vomiting; headache; confusion; depigmentation of hair; skin eruptions; corneal opacity; weight loss; partial alopecia; extraocular muscle palsies; exacerbation of psoriasis, eczema, and other exfoliative dermatoses; myalgias; photophobia

Rare: irreversible retinal injury (especially when total dosage exceeds 100 grams); discoloration of nails and mucus membranes; nerve-type deafness; peripheral neuropathy and myopathy; heart block; blood dyscrasias; hematemesis

CLARITHROMYCIN (*Biaxin*, and generics)

Occasional: nausea; diarrhea; abdominal pain; abnormal taste; headache; dizziness

Rare: reversible dose-related hearing loss; pseudomembranous colitis; pancreatitis; torsades de pointes

CLINDAMYCIN (*Cleocin*, and generics)

Frequent: diarrhea; allergic reactions

Occasional: pseudomembranous colitis, sometimes severe, can occur even with topical use

Rare: blood dyscrasias; esophageal ulceration; hepatotoxicity; arrhythmia due to QTc prolongation

CROTAMITON *(Eurax)*

Occasional: rash

DAPSONE

Frequent: rash; transient headache; GI irritation; anorexia; infectious mononucleosis-like syndrome

Occasional: cyanosis due to methemoglobinemia and sulfhemoglobinemia; other blood dyscrasias, including hemolytic anemia; nephrotic syndrome; liver damage; peripheral neuropathy; hypersensitivity reactions; increased risk of lepra reactions; insomnia; irritability; uncoordinated speech; agitation; acute psychosis

Rare: renal papillary necrosis; severe hypoalbuminemia; epidermal necrolysis; optic atrophy; agranulocytosis; neonatal hyperbilirubinemia after use in pregnancy

DIETHYLCARBAMAZINE CITRATE *(Hetrazan)*

Frequent: allergic or febrile reactions, which may be severe, in patients with microfilaria in the blood or the skin; GI disturbance

Rare: encephalopathy

DILOXANIDE FUROATE *(Furamide)*

Frequent: flatulence

Occasional: nausea; vomiting; diarrhea

Rare: diplopia; dizziness; urticaria; pruritus

EFLORNITHINE (Difluoromethylornithine, DFMO, *Ornidyl*)

Frequent: anemia; leukopenia

Occasional: diarrhea; thrombocytopenia; seizures

Rare: hearing loss

FLUCONAZOLE (*Diflucan*, and generics)

Occasional: nausea; vomiting; diarrhea; abdominal pain; headache; rash; increased aminotransferases

Rare: severe hepatic toxicity; exfoliative dermatitis; anaphylaxis; Stevens-Johnson syndrome; toxic epidermal necrolysis; hair loss

FLUCYTOSINE *(Ancobon)*

Frequent: blood dyscrasias, including pancytopenia and fatal agranulocytosis; GI disturbance, including severe diarrhea and ulcerative colitis; rash; hepatic dysfunction

Occasional: confusion; hallucinations

Rare: anaphylaxis

FURAZOLIDONE *(Furoxone)*

Frequent: nausea; vomiting

Occasional: allergic reactions, including pulmonary infiltration; hypotension; urticaria; fever; vesicular rash; hypoglycemia; headache

Rare: hemolytic anemia in G6PD deficiency and neonates; disulfiram-like reaction with alcohol; MAO-inhibitor interactions; polyneuritis

IODOQUINOL (*Yodoxin*, and generics)

Occasional: rash; acne; slight enlargement of the thyroid gland; nausea; diarrhea; cramps; anal pruritus

Rare: optic neuritis, atrophy and loss of vision; peripheral neuropathy after prolonged use in high dosage (for months); iodine sensitivity

ITRACONAZOLE (*Sporanox*, and generics)

Occasional: nausea; epigastric pain; headache; dizziness; edema; hypokalemia; rash; hepatic toxicity

Rare: congestive heart failure

IVERMECTIN – oral *(Stromectol)*

Occasional: Mazzotti-type reaction seen in onchocerciasis, including fever; pruritus; tender lymph nodes; headache; and joint and bone pain

Rare: hypotension

IVERMECTIN – lotion *(Sklice)*

Occasional: conjunctivitis; ocular hyperemia; eye irritation; dandruff; burning sensation of the skin

KETOCONAZOLE (*Nizoral*, and generics)

Frequent: nausea; vomiting

Occasional: decreased testosterone synthesis; gynecomastia; oligospermia and impotence in men; abdominal pain; rash; hepatitis; pruritus; dizziness; constipation; diarrhea; fever and chills; photophobia; headache

Rare: fatal hepatic necrosis; liver injury with jaundice; transient elevated transaminase; severe epigastric burning and pain; may interfere with adrenal function; anaphylaxis

MALATHION *(Ovide)*

Occasional: local irritation

MEBENDAZOLE *(Vermox)*

Occasional: diarrhea; abdominal pain

Rare: leukopenia; agranulocytosis; hypospermia

MEFLOQUINE *(Lariam)*

Frequent: vertigo; lightheadedness; nausea; other GI disturbances; nightmares; visual disturbances; headache; insomnia

Occasional: confusion

Rare: psychosis; hypotension; convulsions; coma; paresthesias

MEGLUMINE ANTIMONIATE *(Glucantime)*

Similar to sodium stibogluconate

MELARSOPROL *(Mel B)*

Frequent: myocardial damage; albuminuria; hypertension; colic; Herxheimer-type reaction; encephalopathy; vomiting; peripheral neuropathy

Rare: shock

METRONIDAZOLE (*Flagyl,* and generics)

Frequent: nausea; headache; anorexia; metallic taste

Occasional: vomiting; diarrhea; insomnia; weakness; dry mouth; stomatitis; vertigo; tinnitus; paresthesias; rash; dark urine; urethral burning;

disulfiram-like reaction with alcohol; candidiasis

Rare: pseudomembranous colitis; leukopenia; pancreatitis; seizures; peripheral neuropathy; encephalopathy; cerebellar syndrome with ataxia, dysarthria and MRI abnormalities

MICONAZOLE *(Monistat)*

Occasional: phlebitis; thrombocytosis; chills; intense, persistent pruritus; rash; vomiting; hyperlipidemia; dizziness; blurred vision; local burning and irritation with topical use

Rare: anemia; thrombocytopenia; hyponatremia; renal insufficiency; anaphylaxis; cardiac and respiratory arrest with initial dose

MILTEFOSINE *(Impavido)*

Frequent: nausea; vomiting; diarrhea; motion sickness; increased creatinine

NICLOSAMIDE *(Niclocide)*

Occasional: nausea; abdominal pain

NIFURTIMOX *(Lampit)*

Frequent: anorexia; nausea; vomiting; gastric pain; insomnia; headache; vertigo; excitability; myalgia; arthralgia; peripheral polyneuritis

Rare: convulsions; fever; pulmonary infiltrates;

pleural effusion

NITAZOXANIDE *(Alinia)*

Occasional: GI disturbance; headache

Rare: yellow discoloration of sclera; allergic reactions; increased creatinine; dizziness; flatulence; malaise; salivary gland enlargement; discolored urine; anemia; leukocytosis

ORNIDAZOLE *(Tiberal)*

Occasional: dizziness; headache; GI disturbance

Rare: reversible peripheral neuropathy

OXAMNIQUINE *(Vansil)*

Occasional: headache; fever; dizziness; somnolence and insomnia; nausea; diarrhea; rash; increased aminotransferases; ECG changes; EEG changes; orange-red discoloration of urine

Rare: seizures; neuropsychiatric disturbances

PAROMOMYCIN (aminosidine; *Humatin*)

Frequent: GI disturbance with oral use

Rare: eighth-nerve damage (mainly auditory) and renal damage when aminosidine is given IV; vertigo; pancreatitis

PENTAMIDINE ISETHIONATE (*Pentam 300, NebuPent*, and generics)

Frequent: hypotension; hypoglycemia often followed by diabetes mellitus; vomiting; blood dyscrasias; renal damage; pain at injection site; GI disturbance

Occasional: may aggravate diabetes; shock; hypocalcemia; liver damage; cardiotoxicity; delirium; rash

Rare: Herxheimer-type reaction; anaphylaxis; acute pancreatitis; hyperkalemia

PERMETHRIN (*Nix*, and generics)

Occasional: burning; stinging; numbness; increased pruritus; pain; edema; erythema; rash

PRAZIQUANTEL *(Biltricide)*

Frequent: abdominal pain; diarrhea; malaise; headache; dizziness

Occasional: sedation; fever; sweating; nausea; eosinophilia

Rare: pruritus; rash; edema; hiccups

PRIMAQUINE PHOSPHATE

Frequent: hemolytic anemia in G6PD deficiency

Occasional: neutropenia; GI disturbance;

methemoglobinemia

Rare: CNS symptoms; hypertension; arrhythmias

PROGUANIL (*Paludrine; Malarone* [with atovaquone])

Occasional: oral ulceration; hair loss; scaling of palms and soles; urticaria

Rare: hematuria (with large doses); vomiting; abdominal pain; diarrhea (with large doses); thrombocytopenia

PYRANTEL PAMOATE (*Antiminth,* and generics)

Occasional: GI disturbance; headache; dizziness; rash; fever

PYRETHRINS with PIPERONYL BUTOXIDE (*A-200,* and generics)

Occasional: allergic reactions

PYRIMETHAMINE *(Daraprim)*

Occasional: blood dyscrasias; folic acid deficiency

Rare: rash; vomiting; convulsions; shock; possibly pulmonary eosinophilia; fatal cutaneous reactions with pyrimethamine-sulfadoxine *(Fansidar)*

QUINACRINE

Frequent: disulfiram-like reaction with alcohol;

nausea and vomiting; colors skin and urine yellow

Occasional: headache; dizziness

Rare: rash; fever; psychosis; extensive exfoliative dermatitis in patients with psoriasis

QUININE DIHYDROCHLORIDE and QUININE SULFATE

Frequent: cinchonism (tinnitus, headache, nausea, abdominal pain, visual disturbance)

Occasional: deafness; hemolytic anemia; other blood dyscrasias; photosensitivity reactions; hypoglycemia; arrhythmias; hypotension; fever

Rare: blindness; sudden death if injected too rapidly; hypersensitivity reaction with TTP-HUS

SODIUM STIBOGLUCONATE *(Pentostam)*

Frequent: myalgia and arthralgia (typically, large joint, may or may not be symmetric); malaise, fatigue and weakness; headache; anorexia; nausea; increased aminotransferases; increased amylase and lipase; T-wave flattening or inversion

Occasional: abdominal pain; liver damage; bradycardia; leukopenia; thrombocytopenia; rash; vomiting

Rare: diarrhea; pruritus; myocardial damage; hemolytic anemia; renal damage; shock; sudden death

SPIRAMYCIN *(Rovamycine)*

Occasional: GI disturbance

Rare: allergic reactions

SULFONAMIDES

Frequent: allergic reactions (rash, photosensitivity, drug fever)

Occasional: kernicterus in newborn; renal damage; liver damage; Stevens-Johnson syndrome (particularly with long-acting sulfonamides); hemolytic anemia; other blood dyscrasias; vasculitis

Rare: transient acute myopia; pseudomembranous colitis; reversible infertility in men with sulfasalazine; CNS toxicity with trimethoprim-sulfamethoxazole in patients with AIDS

SURAMIN SODIUM

Frequent: vomiting; pruritus; urticaria; paresthesias; hyperesthesia of hands and feet; peripheral neuropathy; photophobia

Occasional: kidney damage; blood dyscrasias; shock; optic atrophy

TETRACYCLINES

(doxycycline – *Vibramycin*, and generics; tetracycline hydrochloride – *Sumycin*, and generics)

Frequent: GI disturbance; bone lesions and staining and deformity of teeth in children up to 8 years old, and in the newborn when given to pregnant women after the fourth month of pregnancy

Occasional: malabsorption; enterocolitis; photosensitivity reactions; increased azotemia with renal insufficiency (except doxycycline, but exacerbation of renal failure with doxycycline has been reported); hepatic injury; parenteral doses may cause serious liver damage, especially in pregnant women and patients with renal disease receiving 1 gram or more daily; esophageal ulcerations; cutaneous and mucosal hyperpigmentation

Rare: allergic reactions, including serum sickness and anaphylaxis; pseudomembranous colitis; blood dyscrasias; drug-induced lupus; autoimmune hepatitis; increased intracranial pressure; fixed-drug eruptions; transient acute myopia; blurred vision; diplopia; papilledema; photoonycholysis and onycholysis; aggravation of myasthenic symptoms with IV injection, reversed with calcium; possibly transient neuropathy; hemolytic anemia

TINIDAZOLE (*Tindamax*, and generics)

Occasional: metallic taste; GI symptoms; rash

Rare: weakness

TRIMETHOPRIM (*Proloprim*, and generics)

Frequent: nausea and vomiting with high doses

Occasional: megaloblastic anemia; thrombocytopenia; neutropenia; rash; fixed drug eruption

Rare: pancytopenia; hyperkalemia

TRIMETHOPRIM/SULFAMETHOXAZOLE (*Bactrim, Septra*, and generics)

Frequent: rash; fever; nausea and vomiting

Occasional: hemolysis in G6PD deficiency; acute megaloblastic anemia; granulocytopenia; thrombocytopenia; pseudomembranous colitis; kernicterus in newborn; hyperkalemia

Rare: agranulocytosis; aplastic anemia; hepatotoxicity; Stevens-Johnson syndrome; aseptic meningitis; fever; confusion; depression; hallucinations; deterioration in renal disease; intrahepatic cholestasis; methemoglobinemia; pancreatitis; ataxia; CNS toxicity in patients with AIDS; renal tubular acidosis; hyperkalemia

Abdominal distention
  in necrotizing enterocolitis, 395
  peritonitis and, 425
  visceral leishmaniasis causing, 1328–1329
Abdominal lymphadenopathy, 156–158
  diagnostic tests for, 157–158
    biopsy, 158
    clinical findings and laboratory tests, 157–158
    imaging studies, 157
  differential diagnosis of, 156–157
  epidemiology of, 156–157, 157*f*
  evaluation of, 156*b*
  therapy for, 158

Abdominal mass, acute pancreatitis and, 419

Abdominal pain

- acute, 173–176
  - associated symptoms of, 173
  - character and relative severity of symptoms of, 173
  - differential diagnosis of, 429*b*
  - history of, 173
  - location of pain, 173
  - migration and radiation sites of, 173
  - physical examination of, 173–174
- acute pancreatitis and, 419
- appendicitis causing, 174, 428
- biliary colic and, 173
- *Blastocystis* and, 1305–1306
- bowel obstruction and, 173
- *Campylobacter jejuni* infections causing, 175
- chronic (CAP) or recurrent (RAP), 176–178
  - approach to diagnosis and management of, 177–178, 177*t*
  - nonorganic causes of, 176
  - nonorganic *versus* organic causes of, 177*t*
  - organic causes of, 176–177
- *Clostridium difficile* infections causing, 175
- *Cyclospora* causing, 1321–1322
- *Diphyllobothrium* infection causing, 1394–1395
- *Entamoeba histolytica* infection causing, 1313, 1313*t*
- enteric infections causing, 175–176
- *Enterobius vermicularis* causing, 175
- epigastric, 173

Epstein-Barr virus (EBV) causing, 176
Escherichia coli causing, 175
examination of, 173–174
functional (FAP), 176
gallbladder disease causing, 175
gastroenteritis causing, 173
granulomatous hepatitis and, 418
Henoch-Schönlein purpura (HSP) causing, 175
hookworm infections causing, 1376
hypogastric, 174
in intra-abdominal abscesses, 433
intussusception causing, 176
mesenteric lymphadenitis causing, 174
pancreatitis causing, 174–175
pelvic inflammatory disease causing, 175
peritonitis and, 173, 425
pneumonia causing, 174
postprandial, 176
pyelonephritis causing, 174
recurrent, 176–178
referred, 174
renal and ureteral colic and, 173
Rocky Mountain spotted fever and, 542
Salmonella causing, 173
specific causes and approach of, 174–176
Streptococcus pyogenes causing, 176
Trichinella spiralis infections causing, 1387
vital signs and habitus of, 173

  volvulus causing, 176
Abdominal radiography, for necrotizing enterocolitis, 395*f*, 396
Abdominal surgery, infection chemoprophylaxis in, 76
Abdominal symptom complexes, 173–178
  acute pain, Abdominal pain
Abdominal trauma, 525
  blunt or penetrating, 525
  infection risk and management following, 524*t*
  pathogens and recommended prophylaxis following, 523*t*
Abelcet, 1490*t*–1498*t*
Abiotrophia, 732–735
  antimicrobial resistance of, 735
  blood culture of, 1425
  endocarditis from, 734
Abortion
  Borrelia infection and, 986
  Leptospira infections causing, 980
  spontaneous
    in congenital rubella syndrome, 1144–1145
    Listeria monocytogenes infection causing, 783
    Ureaplasma urealyticum causing, 1031
    viral infections causing, 558
Abscess, 467–470
  abdominal, Abdominal abscess; Intra-abdominal abscesses
  amebic, Amebic liver abscess
  breast, Breast abscess
  Brodie, 480
  Brucella species (brucellosis) causing, 888

cerebral, Brain abscess

coagulase-negative staphylococci (CoNS) causing, 710

Eikenella corrodens infections and, 860

endocardial, 269

epidural, Epidural abscess

extracerebral, Epidural abscess; Septic venous thrombosis; Subdural empyema

hepatic, 434

intra-abdominal, Intra-abdominal abscesses

lung, Lung, abscess

management of, 468

muscle, Muscle, abscess

Nocardia species causing, 813

pancreatic, 435

parapharyngeal, Parapharyngeal abscess

parietal lobe, 331–332, 332*b*

pathogenesis of, 467–468, 468*b*, 468*t*

periapical, 193

periappendiceal, 787

perineal, 469

perinephric, 346, 435

perirectal, 469–470

peritonsillar, Peritonsillar abscess

psoas muscle, Psoas muscle abscess

renal, Renal abscess

retroperitoneal, Retroperitoneal abscess

retropharyngeal, Retropharyngeal abscess

scalp, Scalp, abscess

- splenic, 434–435
- *Staphylococcus aureus*, *Staphylococcus aureus*
- subdural, Subdural abscess
- subperiosteal, Subperiosteal abscess
- in sweat glands, 469
- temporal lobe, Temporal lobe abscesses
- tubo-ovarian, 368
- visceral, Visceral abscesses

Absidiaceae, 1247–1248

Absolute lymphocyte count (ALC), for SCID, 638

Absolute risk reduction (ARR), 3*t*, 5

Absorption, of drugs, 1482

Abuse, child, Sexual abuse

AC/HS test (differential agglutination), for *Toxoplasma gondii* infection, 1357

Acanthamoeba, 1339–1341, 1341*b*
- clinical manifestations of, 1339
- culture of, 1339
- cutaneous infections of, 1339
  - treatment for, 1341
- description of, 1339
- diagnosis of, 1339–1340
- epidemiology of, 1339
- granulomatous amebic encephalitis from, 312, 315, 1339
- keratitis, 507, 1339, 1340*f*
  - prevention of, 1341
  - treatment for, 509, 1341
- laboratory findings of, 1339–1340

  laboratory testing of, 318*t*–321*t*
  life cycle of, 1340*f*
  mortality of, 1339
  Naegleria fowleri vs., 1338*t*
  prevention of, 1341
  treatment for, 1341
    central nervous system infections, 1341
  trophozoite of, 1339, 1340*f*
Acanthamoeba astronyxis, 1339
Acanthamoeba castellanii, 1339
Acanthamoeba culbertsoni, 1339
Acanthamoeba griffini, 1339
Acanthamoeba hatchetti, 1339
Acanthamoeba lugdunensis, 1339
Acanthamoeba palestinensis, 1339
Acanthamoeba polyphagia, 1339
Acanthamoeba quina, 1339
Acanthamoeba rhysodes, 1339
Acetic acid, treatment for, ear infections, 1545*t*
Acetobacteraceae, 856
Acholeplasma laidlawii, 1028*t*
Acholeplasma oculi, 1028*t*
Achromobacter denitrificans, 856
Achromobacter piechaudii, 856
Achromobacter species, 857
Achromobacter xylosoxidans, 856
Acid-fast bacilli (AFB), 790, *Mycobacterium*
Acidovorax, 857

Acinetobacter baumannii, 851

Acinetobacter calcoaceticus, 851

Acinetobacter haemolyticus, 851

Acinetobacter johnsonii, 851

Acinetobacter junii, 851

Acinetobacter lwoffii, 851

Acinetobacter radioresistens, 851

Acinetobacter species, 851–853

  antimicrobial susceptibility of, 852

  clinical manifestations of, 852

  diagnosis of, 853*b*

  epidemiology of, 851–852, 853*b*

  microbiology of, 851, 853*b*

  treatment of, 852–853, 853*b*

ACIP, Advisory Committee on Immunization Practices (ACIP)

Acne vulgaris, *Malassezia* folliculitis *vs*., 1252

, Acquired immune deficiency syndrome (AIDS), Human immunodeficiency virus (HIV)/AIDS

Acridine orange staining, 1424, 1426

Act A, *Listeria monocytogenes* protein, 782

Actinobacillus, 967

  animal bite infection from, 532

Actinobacillus actinomycetemcomitans, *Aggregatibacter (Actinobacillus) actinomycetemcomitans*

Actinobacillus hominis, 967

Actinobacillus lignieresii, 967

Actinobacillus ureae, 967

Actinomyces, 290, 994*t*, 1020, 1022*b*

  - abdominal actinomycosis from, 1021
  - cervicofacial actinomycosis from, 1020–1021
  - classification of, 989*t*
  - clinical manifestations of, 1020–1022
  - diagnosis of, 1022
  - isolation of, media used for, 1425*t*
  - *Nocardia vs.*, 1020
  - pathogenesis of, 1020
  - pelvic actinomycosis from, 1021
  - subacute or chronic unilateral lymphadenitis from, 142
  - thoracic actinomycosis from, 1021–1022, 1021*f*
  - treatment for, 1022

Actinomyces gerencseriae, 1020

Actinomyces israelii, 1020

Actinomyces meyeri, 1020

Actinomyces naeslundii, 1020

Actinomyces odontolyticus, 1020

Actinomyces viscosus, 1020

Actinomycetes, cell wall and Gram staining of, 690

Actinomycosis, *Actinomyces*

Action potential, of muscle, *Clostridium botulinum* and, 1003

Activated phosphatidylinositol-3-OH kinase delta (PI3Kδ) syndrome (immunodeficiency 14), 619*t*, 623

Activated protein C (aPC), for meningococcal septicemia treatment, 754

Active immunization, Immunization

Active surveillance, 1

Activity, for chronic fatigue syndrome, 1042–1044

Acute chest syndrome, 255
  in sickle hemoglobinopathy, 644
Acute disseminated encephalomyelitis (ADEM), 180, 311, 325–326
  clinical manifestations of, 325
  diagnosis of, 326
  etiologies of, 323*t*
  incidence of, 325
  MRI appearance of, 325–326, 326*f*
  recurrent, 325
  therapy for, 326
Acute epiglottitis, 212–213
  clinical manifestations and diagnosis of, 213, 213*f*
  complications and prognosis of, 213
  epidemiology and pathogenesis of, 212
  etiologic agents of, 212
  management of, 213
Acute febrile illness, HHV-6 causing, 1083, 1083*f*
Acute flaccid myelitis (AFM), 310, 328
  etiologies of, 323*t*
  MRI for, 328*f*
Acute flaccid paralysis (AFP), 1209
Acute focal bacterial nephritis (AFBN), 346
Acute gastroenteritis, treatment for, 832–833
Acute inflammatory demyelinating polyradiculoneuropathy, Guillain-Barré syndrome
Acute lobar nephronia, 346
Acute lymphoblastic leukemia, eosinophilic meningitis from, 342
Acute necrotizing ulcerative gingivitis (ANUG), 194

Acute otitis media (AOM), Otitis media

Acute phase proteins

  cytokines and, 1450–1451, C-reactive protein (CRP)

Acute respiratory distress syndrome (ARDS), sepsis and, 98–99

Acute retinal necrosis syndrome, retinitis and, 512–513

Acute rheumatic fever (ARF), *Streptococcus pyogenes* (group A streptococcus)

Acute suppurative sialadenitis, 197–198

Acute unilateral lymphadenitis, acute bilateral lymphadenopathy lymphadenitis from, 139, 140*t*

Acyclovir, 1551–1556

  adverse effects of, 1554

  chemistry of, 1551–1553

  clinical uses of, 1554–1556, 1555*t*

  dosage of, 1554–1556, 1555*t*

    for impaired renal function, 1490*t*–1498*t*

    in renal dysfunction, 1553, 1553*t*

  drug interactions of, 1554

  for HSV infections, 74, 499, 1062

    compromised hosts, 1064

    cutaneous infections, 1063

    genital infection, 1062–1063

    intrauterine and perinatal infections, 1063

    orolabial infection, 1062

  mechanism of action of, 1551–1553, 1552*t*

  pharmacokinetics of, 1553–1554

  prophylactic, 1554, 1556*t*

  resistance to, 1551–1553, 1552*t*

- spectrum of activity of, 1551–1553
- for VZV infection prevention, 1071
- for VZV infection treatment, 1069, 1070*b*
  - healthy children and adolescents, 1070
  - herpes zoster, 1070
  - immunocompromised patients, 1070
  - intravenous, 1070
  - oral, 1070
  - resistance to, 1069
  - varicella, 1070*b*

Adamantanes
- for influenza treatment, 1185
- influenza virus resistance to, 1186, Amantadine, Rimantadine

Adaptive immune response, Immune response

ADCC, Antibody-dependent cellular cytotoxicity (ADCC)

Adefovir, dosing of, for impaired renal function, 1490*t*–1498*t*

Adefovir dipivoxil, 1551*t*, 1556–1557

Adenitis, Lymphadenitis/lymphadenopathy

Adenoidectomy, 234

Adenopathy, Lymphadenitis/lymphadenopathy

Adenosine deaminase (ADA), deficiency, 639

Adenoviral syndromes, acute bilateral lymphadenopathy lymphadenitis from, 139

Adenoviridae, 1045*t*
- infections, 1046*t*

Adenoviruses, 383, 1097–1101, 1101*b*
- in AIDS, 1100
- antigens, detection, 1100

bronchiolitis from, 234
bronchiolitis obliterans from, 254, 1099
cell culture for, 1100
clinical disease of, 1099–1100, 1099*t*, 1101*b*
cytopathic effects of, 1100
diagnosis of, 1100, 1101*b*
DNA detection, 1100
enteric, 383, 399*t*–405*t*, 1099
    diagnosis of, 1435, 1443
    epidemiologic features of, 386*t*
    epidemiology of, 383–385
    transmission of, 383–384
epidemiology of, 1097*t*–1098*t*, 1098, 1101*b*
fetal/neonatal infections of, 1098*t*, 1100
gastrointestinal infections from, 1098*t*, 1099, Adenoviruses, enteric
genitourinary infections from, 1098*t*, 1099
in hands, 1098
HSCT recipients and, 576
immunization against, 1100
in immunocompromised hosts, 1098*t*, 1100
keratoconjunctivitis from, 1098*t*, 1099
myocarditis from, 271
neurologic infections from, 1099
nosocomial infections of, 1098
optimal tests for, 1437*t*–1440*t*
pharyngitis from, 206
pharyngoconjunctival fever from, 1098*t*, 1099

  - pneumonia from, 241
    - persistent, 250
  - prevention of infections, 1100
  - respiratory, 1098*t*, 1099
    - diagnosis/detection of, 1435
  - subgroups/serotypes of, 1097*t*, 1098
    - disease associated, 1098*t*
    - identification of, 1100
  - transmission of, 1098
  - in transplant recipient, 570
  - treatment of infections for, 1100, 1101*b*
  - virology of, 1101*b*
- Adhesins, *Klebsiella* and, 819
- Aditus ad antrum, 225–226, 226*f*
- Adolescents
  - chronic fatigue syndrome in, 1040
  - HIV infection in, 659–665
    - clinical manifestations of, 660
    - epidemiology of, 659–660, 659*t*
    - opportunistic infections, 675
    - prevention of, 664–665, 664*b*
    - progression of, 660
  - inclusion conjunctivitis of, 504
  - *Mycoplasma hominis* in, 1028
  - *Mycoplasma pneumoniae* in, 1023
  - myopericarditis in, enterovirus causing, 1210
  - pneumonia in, 238–240
    - persistent, 251

  pyogenic arthritis in, 488
  urinary tract infections in, 344
  varicella complications in, 1067
    treatment for, 1069–1070
Adoption, international, Refugee and internationally adopted children
Adrenal insufficiency, chronic fatigue syndrome causing, 1039
Adult seborrheic eczema (ASE), *Malassezia* causing, 1252
Adult T-cell leukemia/ lymphoma (ATLL), 1197
Advisory Committee on Immunization Practices (ACIP), 743
  for hepatitis A virus recommendations, 1217–1218
  for licensure vaccines, 46
Aedes mosquito
  in Chikungunya virus transmission, 1126
  dengue viruses from, 1129
  in Ross River virus transmission, 1126
  yellow fever virus from, 1128
Aerobic bacteria
  bite wound infections from, 533*t*
  normal flora of, 989*t*
Aerococcus, biochemical differentiation of, 747*t*
Aerococcus viridans, 747
Aeromonas, 853–855
  clinical manifestations of, 854
  description of pathogen, 853
  diagnosis and management of, 855*b*
  epidemiology of, 853–854
  gastroenteritis from, 854

  - isolation of, media used for, 1425*t*
  - laboratory findings and diagnosis of, 854
  - prevention of, 855
  - septicemia from, 854
  - skin and soft-tissue infections from, 854
  - treatment for, 854–855
  - uncommon clinical presentations of, 854
- *Aeromonas caviae*, 854
- *Aeromonas hydrophila*, 854
  - inflammatory enteritis from, 389
  - skin and soft-tissue infections and, 854
  - skin infection after trauma from, 523
- Aerophobia, rabies virus causing, 1177–1178
- Aerosol transmission, classification of, 11
- Affective disorder
  - chronic fatigue syndrome causing, 1040, Depression
- African sleeping sickness, *Trypanosoma (Trypanozoon) brucei*
- African tick bite fever, Rickettsiosis
- African trypanosomiasis, *Trypanosoma (Trypanozoon) brucei*
- Agammaglobulinemia, 619*t*, 620–621, 620*b*
  - X-linked, X-linked agammaglobulinemia
- Agar, for culture, Culture media
- Agar dilution, for antimicrobial susceptibility testing, 1463
- Age
  - as risk factors, in urinary tract infections, 343, *see also specific infections*
- , Agglutination test
  - for *Leptospira*, 979, Latex agglutination

Aggregatibacter
  differential characteristics of, 933*t*
  species, 932–934, 967–968
Aggregatibacter (Actinobacillus) actinomycetemcomitans, 967, 1022
  early-onset periodontitis from, 193
  endocarditis from, 967
  isolation of, 967
  treatment for, 967–968
Aggregatibacter (Haemophilus) aphrophilus, 932
Aggregatibacter (Haemophilus) parainfluenzae, *Haemophilus parainfluenzae*
Aggregatibacter (Haemophilus) segnis, 932
AIDS, Human immunodeficiency virus (HIV)/AIDS
Air crescent sign, *Aspergillus* infections and, 1241–1242
Air trapping, in viral pneumonia, 240
Airborne infections, healthcare-associated infections, 11
Airway management, for acute epiglottitis, 213
Airways, upper and middle infections of, 208–215
  clinical features and causative organisms of, 209*t*
Ajellomyces dermatitidis, 1270
Alagille syndrome, 412
Alanine aminotransferase (ALT)
  for HAV infection, 1216, 1216*f*
  for HCV infection, 1138–1140
  for HIV infection, 672–673
Albendazole
  adverse reactions of, 1407
  contraindications for, 1407

for *Giardia intestinalis* (giardiasis), 1319, 1320*t*
for intestinal nematodes, 1570–1571
treatment for
  Ascaris lumbricoides infection, 1572
  baylisascariasis (raccoon roundworm infection), 1572
  capillariasis, 1572
  clonorchiasis, 1572
  cutaneous larva migrans, 1385, 1572
  echinococcosis, 1572
  Echinococcus granulosus, 1407
  Echinococcus multilocularis, 1409
  echinostome infections, 1413
  enterobiasis (pinworm), 1572
  Enterobius vermicularis infections, 1379
  Gnathostoma spinigerum infections, 1384–1385
  gnathostomiasis (cutaneous), 1572
  hookworm, 1572
  lymphatic filariasis, 1391
  Mansonella perstans, 1393
  neurocysticercosis, 1572
  Opisthorchis infection, 1572
  Sarcocystis infection, 1352
  Strongyloides infections, 1380
  strongyloidiasis, 1572
  Taenia solium neurocysticercosis, 1399, 1402*t*
  Toxocara infections, 1383
  toxocariasis, 1572
  Trichinella spiralis infection, 1387

        trichinellosis, 1572
        trichuriasis, 1572
        Trichuris trichiura infections, 1378
Albumin, in nasal secretions, elevated levels in colds of, 200
Albuterol, aerosolized, treatment for, *Bordetella pertussis*, 897
Alcaligenaceae, 856
Alcaligenes faecalis, 856
Alcaligenes species, 856–857
Alexithymia, 1040
Alkaline phosphatase
    elevated, *Cryptosporidium* infections causing, 1307
    for hepatitis A virus infection, 1216
Allergic bronchopulmonary aspergillosis (ABPA), 1238
Allergic reactions
    cyst rupture, 1406
    to pets and animals, 540
    to *Taenia serialis* (coenurosis), 1410
Allergic rhinitis, 166
    diagnosis of, 201
Allylamines, 1533, *see also individual agents*
Alopecia, tinea capitis causing, 1283*f*, 1284
Alopecia areata, 1284
Alphaherpesvirinae, 1055–1056, 1055*t*
Alphaviruses, 1126–1128, 1127*b*–1128*b*
    laboratory diagnosis of, 1127
    prevention of, 1127
Altered mental status, 180–181
    causes of, 180*t*

- in children, 180*t*
- evaluation of, 181
- history of, 180
- physical examination of, 181
- therapy for, 181

Alternaria, 1245–1247

Alveolar echinococcosis, *Echinococcus multilocularis* (alveolar echinococcosis)

Alveolar macrophages, 240

Amantadine
- dosing of, for impaired renal function, 1490*t*–1498*t*
- resistance to, 1552*t*

Amastigotes
- of *Leishmania*, 1323
- of *Trypanosoma (Schizotrypanum) cruzi*, 1369, 1371*f*

AmBisome, dosing of, for impaired renal function, 1490*t*–1498*t*

Ambler classification system, 1470

Ameba, 1316–1317
- free-living, 1336
  - avoidance of, 1338, *Acanthamoeba;*, *Naegleria fowleri*

Amebapore, 1312

Amebiasis, *Entamoeba histolytica*

Amebic colitis (intestinal amebiasis)
- clinical manifestations of, 1313, 1313*f*, 1313*t*
- treatment of, 1315*b*

Amebic liver abscess (ALA)
- clinical manifestations of, 1313–1314, 1314*t*
- treatment of, 1315*b*

Ameboma, 1313
American Academy of Pediatrics (AAP), 741–742
  in acute otitis media, 219–221
  in *Neisseria meningitidis* vaccines, 751–752
  in rubella-containing vaccination, 1147
American Academy of Pediatrics *Red Book: Report of the Committee on Infectious Diseases*, 71
American Heart Association (AHA), in endocarditis
  surgical intervention for, guidelines of, 269, 269*t*
  therapeutic recommendations of, 735
American Thoracic Society (ATS), diagnostic criteria for NTM pulmonary infection, 810
American trypanosomiasis, *Trypanosoma (Schizotrypanum) cruzi*
American Veterinary Medical Association (AVMA), 539–541
Amikacin, 1521
  dosage for, 1527*t*–1531*t*
  for endophthalmitis, 516*t*
  pharmacokinetics of, 1490*t*–1505*t*
  spectrum of activity of, 1506*t*–1511*t*
  treatment for
    childhood TB, 802*t*
    eye infections, 1543*t*
    Francisella tularensis infections, 925
    Klebsiella, 820–821
    Proteus, *Providencia*, *Morganella* infections, 834
Aminoglycosides, 1520–1521
  combination therapy with, 1469
  dosage for, 1490*t*–1498*t*, 1527*t*–1531*t*

  - for infections after burn, 531
  - modifying enzymes, in *Pseudomonas aeruginosa*, 869–870
  - pharmacokinetics of, 1499*t*–1505*t*
  - resistance to, 1468*t*, 1469–1470
    - screening for, 1475
  - spectrum of activity of, 1506*t*–1511*t*
  - treatment for
    - endocarditis, 268
    - *Proteus, Providencia, Morganella* infections, 834
    - *Staphylococcus aureus*, 705
    - viridans streptococci, 734–735
  - for urinary tract infections, 345

Aminopenicillins, 1514–1515
  - dosage for, 1527*t*–1530*t*
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*

p-Aminosalicylic acid, Para-aminosalicylic acid

Aminotransferases, Alanine aminotransferase (ALT)

Amnionitis, *Mycoplasma hominis* infection and, 1028

Amniotic fluid, in *Toxoplasma gondii* infection diagnosis, 1357

Amniotic membrane, rupture of, in *Mycoplasma hominis* infection, 1028

Amoxicillin, 742, 1514
  - dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*
  - treatment for
    - acute otitis media, 220

    - acute sinusitis, 232
    - *Bacillus anthracis* infections, 771
    - GAS pharyngitis, 206
    - pneumonia, 243
- Amoxicillin-clavulanate, 741–742
  - dosage for, 1527*t*–1530*t*
  - spectrum of activity of, 1506*t*–1511*t*
- Amoxicillin with potassium clavulanate, for acute bacterial sinusitis, 232–233
- AmpC β-Lactamase, β-Lactamase
- Amphibians, diseases associated with, 538
- Amphotec, dosing of, for impaired renal function, 1490*t*–1498*t*
- Amphotericin B, 1533–1536
  - adverse effects of, 1583
  - clinical experience of, 1535–1536
  - dosing of, for impaired renal function, 1490*t*–1498*t*
  - lipid-preparations, for *Blastomyces dermatitidis* (blastomycosis), 1273
  - liposomal
    - for *Aspergillus* infections, 1243
    - for *Blastomyces dermatitidis* (blastomycosis), 1274
    - for *Histoplasma capsulatum*, 1264–1265
  - mechanism of action of, 1533–1534
  - minimum inhibitory concentration (MIC) of, 1432
  - pediatric data of, 1535–1536
  - pharmacology of, 1534–1535
  - toxicity of, 1534–1535
    - nephrotoxicity, 1534

treatment for
  Aspergillus sinusitis, 590
  Candida infections, 1235
  Coccidioides immitis (coccidioidomycosis), 1280
  cryptococcal meningitis, 1257–1258
  eumycotic mycetoma, 1289–1290
  fungal endophthalmitis, 515, 516*t*
  leishmaniasis, 1568
  mucosal infection, 1572
  Naegleria fowleri infection, 1338
Amphotericin B deoxycholate
  for *Aspergillus* infections, 1243
  for *Blastomyces dermatitidis* (blastomycosis), 1273
  for *Cryptococcus* infection, 1258
  for mucormycosis, 1247–1248
  for visceral (kalaazar) leishmaniasis, 1572
Ampicillin, 1514
  adverse effect of, 284–285
  dosage for, 1490*t*–1498*t*, 1527*t*–1531*t*
  MIC of, 1429*t*
  pharmacokinetics of, 1499*t*–1505*t*
  resistance to, 283
    Haemophilus influenzae, 930
  spectrum of activity of, 1506*t*–1511*t*
  structure of, 1512*f*
  treatment for
    Haemophilus infections, 934
    infants with fever without localizing signs, 117

    - *Kingella kingae*, 948
    - *Listeria monocytogenes* infections, 784
    - rash in EBV infection from, 1090
    - *Salmonella* infections, 841, 841*t*
    - *Shigella* infections, 845, 845*t*
    - urinary tract infections, 345
- Ampicillin-sulbactam
  - dosage for, 1527*t*–1530*t*
  - for orbital infections, 521–522
  - spectrum of activity of, 1506*t*–1511*t*
- Amplified fragment length polymorphism (AFLP) analysis
  - for bacterial identification, 691
  - for *Malassezia*, 1251
- , Amyloidosis, 127
- Anaerobic bacteria, 987
  - acute bilateral lymphadenopathy lymphadenitis from, 140
  - antimicrobial agents of, 994–995
  - antimicrobial susceptibility testing for, 1431
  - bite wound infections from, 532, 533*t*
  - classification of, 987–988, 987*t*
  - clinical clues and approach of, 991–992, 991*t*
  - cocci, Gram-positive, Anaerobic gram-positive cocci
  - collection methods and transport media in, 1422*t*
  - direct examination of, 992–993
  - drugs of choice for infections caused by, 994*t*
  - facultative, 987*t*
    - establishment of normal flora, 988
  - genera of clinically significant, 988*t*

Gram-negative bacilli, Anaerobic Gram-negative bacilli (AGNB)
Gram-positive bacilli, non-spore-forming, Anaerobic gram-positive nonsporulating bacilli
Gram-positive cocci, Anaerobic gram-positive cocci
infections commonly involving, 992*t*
isolation of, media used for, 1425*t*
mechanisms of resistance in, 993
media used for recovery of, 993*t*
methods for collection of specimen for, 992*t*
microbiologic methods of, 992–993
necrotizing enterocolitis from, 396
necrotizing pneumonia and lung abscess from, 248
normal flora of, 987
  establishment, 988, Flora
oxygen sensitivity in, 987–988
pathogenesis of, 990–991
pelvic inflammatory disease from, 367
pericarditis from, 274
primary isolation of, 993
principles of management of, 993–994
renal abscesses from, 346
sinusitis from, 232
specimen collection of, 992
specimen transport system for, 992*t*
spore-forming, 994
strict anaerobes, 987–988, 987*t*
susceptibility testing of, 993
transport of, 992

  treatment for, 993–995, *see also individual genera*

Anaerobic blood agar, 1424*t*

Anaerobic cocci, 1018–1019

  clinical manifestations of, 1018–1019

  pathophysiology and predisposing conditions to, 1018

  synergy for, 1018

  treatment for, 1019

Anaerobic Gram-negative bacilli (AGNB), 1012–1014

  bloodstream infection from, 1014

  cervical lymphadenitis and cysts from, 1013

  clinical manifestation of, 1012–1014

  deep neck infections from, 1012

  genera included in, 1012

  genital tract infections from, 1013

  head and neck infections from, 1012–1013

    after operations, 1013

  intra-abdominal infections from, 1013

  mastoiditis from, 1012

  osteomyelitis from, 1013–1014

  otitis media from, 1012

  pathophysiology of, 1012

  peritonsillar, lateral pharyngeal, and retropharyngeal abscesses from, 1012

  pleuropulmonary infections from, 1013

  prediction of pathogens, 1012–1014

  prevention for, 1014

  pyogenic arthritis from, 1013–1014

  sinusitis from, 1013

skin and soft tissue infections from, 1013
tonsillitis from, 1013
treatment for, 1014, *Bacteroides;*, *Prevotella*
Anaerobic gram-positive cocci, 988, *Peptostreptococcus*
Anaerobic gram-positive nonsporulating bacilli, 1019–1022, *Actinomyces;*, *Propionibacterium*
Anaerococcus, 1018
Anal discharge, proctitis, proctocolitis, and enteritis syndrome, 350, 350*t*–351*t*
Anal intercourse, 350
Anal pruritus, *Taenia solium* causing, 1398–1399
Analytic epidemiology, 2–7
case-control studies, 3*t*, 4
cohort studies, 2–3, 3*t*, 4*f*
cross-sectional studies, 3–4
ecologic or trend studies, 2
observational studies, 2
study design, 2–4
Anaphylaxis
urticaria with, 456, Allergic reactions
Anaplasma, 918–923
clinical manifestations of, 919*t*, 920–921
considerations in, 922
description of, 918–919
diagnostic tests for, 921, 922*b*–923*b*
differential diagnosis of, 921
epidemiology of, 919–920
generalized lymphadenopathy from, 131

  laboratory findings of, 921
  microbiology of, 922
  prevention of, 922
  thrombocytopenia from, 1458
  treatment for, 921–922
Anaplasma phagocytophila, laboratory testing of, 318*t*–321*t*
Anaplasma phagocytophilum, 918
  Babesia infection with, 1299
  Borrelia burgdorferi and, 920
  cross-reactivity in, 543–545
  detection of, 921
  human granulocytic anaplasmosis from, 543*t*, 919
  morulae and, 918
  in pregnancy, 922
  transmission of, by ticks, 542
Anaplasmataceae, 690, 918–923
Ancylostoma braziliense, 1385
  cutaneous larva migrans from, 1385
Ancylostoma caninum, 1376–1377, 1385
  clinical features of, 1374*b*, 1377
  cutaneous larva migrans from, 1385, 1385*f*
Ancylostoma ceylanicum, 1373–1374
  clinical manifestations of, 1374*b*, 1376–1377
  epidemiology of, 1376
Ancylostoma duodenale, 1293*t*, 1373
  clinical manifestations of, 1374*b*, 1376
  epidemiology of, 1376
  infection route of, 1373–1374

  neonatal infection from, 1374*t*, Hookworms
Anelloviridae, 1045*t*
  infections, 1046*t*
Anemia
  in acute infection, 1451
  Babesia and, 1299
  Brucella species (brucellosis) causing, 888
  in chronic infection, 1451
  hemolytic, Hemolytic anemia
  HIV infection causing, 673
  hookworm infections causing, 1376
  iron deficiency, Iron deficiency anemia
  Leptospira infections causing, 979
  megaloblastic, *Diphyllobothrium* infection causing, 1394
  Neisseria meningitidis and, 753
  Plasmodium infections causing, 1344
  Trichuris trichiura infections causing, 1378
  visceral leishmaniasis causing, 1329
Aneurysm
  coronary artery, Coronary artery aneurysm
  Trypanosoma cruzi infections and, 1371
Angina, Ludwig, 197
Angioedema, 456
Angiostrongylus, 1384
  description and life cycle of, 1384
  encephalitis from, 312
  eosinophilic meningoencephalitis from, 1384
Angiostrongylus cantonensis, 1384

  chronic meningitis from, 292–293, 292*t*
  clinical features of, 1384
  CNS migration of, 341
  diagnosis of, 341
  eosinophilic meningitis from, 339, 340*t*, 341
  intermediate hosts of, 341
  life cycle of, 341
  optic neuritis from, 325
Angiostrongylus costaricensis, 1384
  clinical features of, 1384
Anidulafungin, 1540–1541
  clinical experience of, 1540–1541
  dosing of, for impaired renal function, 1490*t*–1498*t*
  pediatric data of, 1540–1541
  pharmacology of, 1540
  toxicities of, 1540
Animal(s)
  allergies from, 540

- Antimotility agents
  - avoidance of, in shigellosis, 845, Antiperistaltic agents
- Antimycobacterial therapy, Antituberculosis agents
- Antinuclear antibody, 1459*t*
- Antiparasitic agents, 1567–1587
  - principal adverse effects of, 1567–1568
  - treatment for
    - eosinophilic meningitis, 342
    - helminthic infections, 1570
    - intestinal nematodes, 1570–1571
    - luminal protozoa, 1567–1568
    - malaria, 1569
    - systemic nematodes, 1571
    - trematodes and cestodes, 1571–1572, *see also individual drugs*
- Antiperistaltic agents
  - for foodborne disease/waterborne disease, 407, Antimotility agents
- Antipseudomonal agents, 870
- Antipyretic therapy, 94
- Antiretroviral therapy

  HAART, Highly active antiretroviral therapy (HAART)
  for mother-to-child transmission of HIV, 661–662
  pharmacokinetic-pharmacodynamic relationships for, 1489*t*, Human immunodeficiency virus (HIV)/AIDS
Antistaphylococcal agents, treatment for, *Staphylococcus aureus*, 703–705
Antistreptococcal antibody titers, 206
α_1-Antitrypsin deficiency
  acute hepatitis and, 412
  chronic hepatitis and, 416
Antituberculosis agents, 801–803, 803*t*
  for children, 802*t*
  ethambutol as, 802–803
  isoniazid as, 801
  pyrazinamide as, 801–802
  rifampin as, 801
  for tuberculous osteomyelitis, 485, *see also individual drugs*
Antitussives, 201
Antiviral agents, 1551–1567, 1552*t*
  for bronchiolitis, 237
  effects of, immune function and viral reservoirs, 666–667
  inorganic pyrophosphate analogues as, 1564–1565
  neuraminidase inhibitors as, 1565–1567
  nucleoside/nucleotide analogues as, 1551–1564, 1553*t*
  pharmacokinetic-pharmacodynamic relationships for, 1489*t*
  prophylactic therapy and, 1556*t*
  resistance to, 1552*t*, Antimicrobial drug resistance, Antiretroviral therapy, individual agents

Antiviral drug resistance, for cytomegalovirus, 1079

Antrum, 225–226

Aortic dissection, chest pain with, 192*t*

APECED, 639, 640*t*

Aphthous ulcers, HIV infection causing, 679

Apicomplexa, 1292

Aplastic crisis, transient, parvovirus B19 causing, 1115, 1116*f*, 1116*t*, 1117

Apnea, RSV-related, 236

Apophysomyces, 1247–1248

Apophysomyces elegans, 1249

Apoptosis, of host cells, *Entamoeba histolytica* causing, 1312

Appendectomy, 430

  interval, 431

  laparoscopic and open techniques for, 430

  postoperative antibiotics for, 431

Appendiceal rupture, 174, 432

Appendicitis, 174, 428–432

  abdominal pain and, 173

  Balantioides coli infections causing, 1303

  clinical manifestations of, 429, 429*t*

  complicated, 431–432

  diagnostic imaging of, 429–430

  differential diagnosis of, 429

  , epidemiology of, 428

  etiology of, 428–429

  in infants, 174

  laboratory testing of, 429

  - left-sided, 174
  - management of, 430–431
    - nonoperative, 431
    - operative, 430–431
  - pathogenesis of, 428
  - perforated
    - common organisms in, 428*b*
    - intra-abdominal abscess, 432–433
    - rate of, 430–431
  - retrocecal, 355
  - scoring system of (MANTRELS Score), 429–430, 430*t*
  - sequence of events in, 174*b*
- "Apple core" lesions, *Entamoeba histolytica* infection causing, 1313
- Aqueous humor, infection, Endophthalmitis
- D-Arabinitol/L-arabinitol, in *Candida* spp., 1235
- Arachnoid cyst, with sinus tract, 299*f*
- Arboviruses
  - arthritis from, 491
  - aseptic meningitis from, 302
  - chronic fatigue syndrome from, 1038*b*
  - diagnosis/detection of, 1445
  - encephalitis from, 311
  - exanthems from, 446*b*
  - optimal tests for, 1437*t*–1440*t*
  - pathogenesis of, 303
  - transmission of, 302
- *Arcanobacterium haemolyticum*, 452, 768–770, 769*b*
  - pharyngitis from, 202

Archeozoa, 1292–1293, 1292*b*, 1292*t*
  evolutionary transition of, 1292
Arenaviridae, 1045*t*
  infections, 1046*t*
Arenaviruses, 1190–1195, 1195*b*
  aseptic meningitis from, 302
  clinical laboratory findings of, 1192, 1193*t*
  clinical manifestations of, 1192–1193, 1192*f*
  contact tracing for, 1195
  differential diagnosis of, 1193
  epidemiology of, 1190
  hospital discharge and management of convalescence in, 1194
  human-to-human transmission of, 1190
  laboratory testing for, 1193
  lymphocytic choriomeningitis virus, 1192–1193, 1194*f*
  maintenance in nature of, 1190
  pathobiology of, 1190–1192
  personal protection and nursing precautions for, 1195
  postexposure prophylaxis for, 1195
  prevention of, 1195
  reservoir and vector control for, 1195
  transmission to humans of, 1190, 1191*t*
  treatment of, 1193–1194
  vaccines for, 1195
  viral hemorrhagic fever from, 1192
Arginine, in *Mycoplasma hominis*, 1028–1029
Arithmetic mean, 5
Artemether, for fascioliasis, 1416

Artemether/lumefantrine, 1569, 1572
  adverse effects of, 1583
  for *Plasmodium* infections, 1345*t*–1346*t*, 1347
Artemisinin, antimalarial therapy, 1569
Arteriovenous fistula infection, *Rothia dentocariosa* causing, 787
Artesunate
  adverse effects of, 1583
  for fascioliasis, 1416
Arthritis
  anaerobic cocci causing, 1019
  Aspergillus species causing, 492
  bacterial, Arthritis, pyogenic (bacterial)
  Blastomyces dermatitidis causing, 492
  Borrelia burgdorferi (Lyme disease) causing, 983, 984*b*
  Candida species causing, 492
  Coccidioides immitis (coccidioidomycosis) and, 492, 1279
  Cryptococcus neoformans causing, 492
  fungi causing, 492
  gonococcal, 490
  in Henoch-Schönlein purpura, 175
  Histoplasma capsulatum causing, 492
  infectious, Arthritis, pyogenic (bacterial)
  limb pain from, 185
  Lyme, 490–491, 542–543
  Mycobacterium species causing, 491–492
  Mycoplasma pneumoniae causing, 1024*t*, 1025
  Mycoplasma species causing, 491
  neonatal, 490

noninfectious inflammatory causes of, 186
poststreptococcal reactive, 722–723
pyogenic (bacterial), 185–186, 187*t*, 487–490
    anaerobic gram-negative bacilli causing, 1013–1014
    bite wound complication and, 536
    Brucella species (brucellosis) causing, 487, 887
    in burn patients, 529
    clinical manifestations of, 487–488
    Corynebacterium diphtheriae causing, 775
    diagnosis of, 488, 488*t*
    disseminated gonococcal infection causing, 761
    Haemophilus influenzae type b (Hib) causing, 487
    joints involved in, 487, 488*t*
    Kingella kingae causing, 487, 946
    N. meningitidis causing, 487
    Neisseria gonorrhoeae causing, 761
    pathophysiology of, 487
    prognosis of, 490
    Pseudomonas aeruginosa causing, 487
    Staphylococcus aureus causing, 185, 487, 697
    Streptococcus agalactiae (Group B *Streptococcus*) and, 725
    Streptococcus pneumoniae causing, 487
    Streptococcus pyogenes causing, 487
    transient synovitis and, 496
    treatment for, 488–490, 489*t*–490*t*
reactive, 186, 187*t*, 492–493
    after *Neisseria meningitidis* infections, 755
    bacteria associated with, 492*b*

    - *Campylobacter* causing, 901
    - enteric disease and, 408
    - polyarticular, 493
    - *S. pyogenes* causing, 493
    - *Salmonella* gastroenteritis and, 839
    - *Shigella* infections causing, 844
    - *Yersinia enterocolitica* causing, 848, Reiter syndrome
  - rheumatoid, Rheumatoid arthritis
  - septic, Arthritis, pyogenic (bacterial)
  - *Sporothrix schenckii* causing, 492
  - varicella complication and, 1067
  - viral, 491
- Arthritis-dermatitis syndrome (disseminated gonococcal infection), 762
- Arthroconidia, of *Coccidioides*, 1276, 1276*f*
- Arthropathy, acquired rubella and, 1147
- Arthroscopy, for pyogenic arthritis, 488–489
- Arthus-type hypersensitivity, diphtheria toxoid and, 777–778
- *Asaia* species, 858–859
- Ascariasis, *Ascaris lumbricoides*
- *Ascaris lumbricoides*, 1293, 1293*t*, 1374–1376
  - cholecystitis and cholangitis from, 421
  - chronic infections from, 1374
  - clinical manifestations of, 1374*b*, 1375, 1375*f*
  - differential diagnosis of, 1375
  - eggs of, 1374*f*
  - eosinophilia from, 1454–1456
  - epidemiology of, 1374–1375

  infection route of, 1373–1374
  intestinal obstruction from, 1375
  laboratory findings and diagnosis of, 1374*f*, 1375
  life cycle of, 1374–1375
  neonatal infection from, 1374*t*
  prevention of, 1375–1376
  treatment of, 1375
Ascites, 647
  transport systems and media inoculated routinely in, 1423*t*
Aspartate transaminase, increased, *Rickettsia felis* causing, 960
Aspergilloma, pulmonary, 1240
Aspergillosis, allergic bronchopulmonary and, 1240
Aspergillus, 1238–1244
  aflatoxin for, 1238
  allergic bronchopulmonary, 1240
  antigens to, 1242
  arthritis from, 492
  brain abscess from, 329, 1239
  burn wound infections from, 529
  cerebral infection and, 1239
  chronic necrotizing pulmonary aspergillosis, 1240
  chronic pulmonary aspergillosis, 1240
  clinical manifestations of, 1238–1240, 1244*b*
  colonization with, 1238
  conidia of, 1238
  cutaneous infection, 1239–1240
  diagnosis of, 1241–1243, 1244*b*
    bronchoalveolar lavage, 1242

  culture, 1241
  galactomannan antigen testing, 1242
  (1,3)-β-D-glucan, 1242–1243
  imaging, 1241–1242
  polymerase chain reaction, 1243
  serologic testing, 1242–1243
disseminated disease of, 1238
endocarditis from, management, 268
epidemiology of, 1240–1241, 1244*b*
fungemia, 1241
galactomannan antigen, detection of, 1432
growth of, 1241
host defense mechanisms of, 1238
in HSCT recipients, 574–575, 575*f*
hyphae of, 1238
immunocompromised, 1238
infection, after heart transplantation, 569
invasive sinusitis, 1239
microbiology of, 1238
mortality of, 1240–1241
osteomyelitis from, 485
pneumonia from, 251, 255
  diagnosis of, 258
  transplant-associated, 258
prognosis of, 1243
pulmonary aspergilloma, 1240
pulmonary infection of, 1238–1239, 1239*f*
reproduction (sexual/asexual) in, 1238

- risk factors of, 1240–1241
- semi-invasive aspergillosis, 1240
- sinusitis from, 1239
- treatment for, 1243, 1244*b*
- whole-genome sequencing of, 1238

Aspergillus fumigatus, virulence of, 1238

Aspergillus nidulans, 1238
- pulmonary disease and, 1239

Aspergillus terreus, 1238
- adventitious sporulation of, 1241

Aspiration pneumonia, 594

Aspirin
- avoidance of, in dengue virus, 1129
- for Kawasaki disease treatment, 1036

Asplenia, 646–647, 739
- *Capnocytophaga canimorsus* causing, 905
- congenital, 646
- etiologic agents in, 646
- functional, 646
- infection chemoprophylaxis for, 76–77
- infection risk of, 77
- management of, 646
- pathogenesis of, 646
- prevention of, 646–647

Association measures and risk, 3*t*, 5

Asteroid bodies, of *Sporothrix schenckii*, 1254

Asthma
- bronchiolitis linked to, 237

exacerbations
    Chlamydophila (Chlamydia) pneumoniae causing, 907
    human metapneumovirus and, 1167–1168
    Mycoplasma pneumoniae infections and, 1024
  persistent pneumonia linked to, 253–254, 254*f*
  pneumonia linked to, 244
Astroviridae, 1045*t*
  infections, 1046*t*
, Astroviruses, 383, 1224–1226, 1225*b*–1226*b*
  clinical manifestations of, 1225
  description of, 1224, 1225*f*
  diagnosis/detection of, 1443
  epidemiology of, 383–385, 1224–1225
  gastroenteritis from, 383, 1224
    epidemiologic features of, 386*t*
  laboratory findings and diagnosis of, 1225
  optimal tests for, 1437*t*–1440*t*
  prevention of, 1225
  serotypes of, 383
  treatment for, 1225
Ataxia, 181–182
  cerebellar, 325
  in children, features of causes of, 181*t*
  chronic, 182
  history of, 181–182
  physical examination of, 182
  therapy for, 182
Ataxia-telangiectasia, 639, 640*t*

Atazanavir, 682*t*, 1490*t*–1498*t*

Atelectasis, in infant botulism, 1004

Atherosclerotic cardiovascular disease, *Chlamydophila (Chlamydia) pneumoniae* causing, 907

ATM gene, 639

Atopic dermatitis, tinea capitis causing, 1284

Atovaquone

- for *Babesia* (babesiosis), 1300, 1572
- for *Plasmodium* (malaria), 1569–1570
- for *Pneumocystis jirovecii* infection, 1268*t*
- for *Toxoplasma gondii*, 1359, 1361, 1361*t*
- for toxoplasmosis CNS disease, 1572

Atovaquone-proguanil, 1572

- adverse effects of, 1347
- for *P. vivax*, 1572
- for *Plasmodium* infections, 1345*t*–1346*t*, 1347
  - prophylaxis, 1347, 1348*t*

Attack rates (AR), 1

Attributable risk, 5

Autoimmune disorders

- antinuclear antibody to, 1459*t*
- chronic hepatitis and, 415
- generalized lymphadenopathy from, 135
- rheumatoid factor in, 1459*t*

Autoimmune hepatitis (AIH), 412

Autoimmune neuropsychiatric disorders, pediatric, streptococcal infections and, 722

Autoimmune polyendocrinopathy-candidiasis-ectodermal dysplasia (APECED) syndrome, APECED

Autoimmune regulator *(AIRE)* gene, 639

Autoinflammatory disorders

  chronic hepatitis and, 415

  generalized lymphadenopathy from, 135

Autoinflammatory syndrome, 122, Hereditary periodic fever syndromes

Autolysin, 737

Autonomic dysfunction, infant botulism causing, 1002

Autosensitization reaction, 465–466, 465*b*

Avian influenza (H5N1 strain), 1188

  diagnosis of, 1442

Avoidant behavior, chronic fatigue syndrome causing, 1040

Axillary lymphadenopathy, *Bartonella henselae* infection causing, 883*f*–884*f*

Azalides

  dosage for, 1527*t*–1530*t*

  pharmacokinetics of, 1499*t*–1505*t*

  spectrum of activity of, 1506*t*–1511*t*

Azithromycin, 1518–1519

  adverse effects of, 1583

  dosage for, 1490*t*–1498*t*, 1527*t*–1531*t*

  pharmacokinetics of, 1499*t*–1505*t*

  spectrum of activity of, 1506*t*–1511*t*

  treatment for

    acute otitis media, 218

    Babesia (babesiosis), 1572

    bite wound infections, 536

    Bordetella pertussis, 896, 897*t*

    - *Campylobacter* infections, 904
    - *Chlamydia trachomatis*, 912
    - chlamydial conjunctivitis, 498
    - eye infections, 1542*t*–1543*t*
    - *Haemophilus ducreyi* (chancroid), 933
    - *Klebsiella (Calymmatobacterium) granulomatis*, 823–824
    - *Legionella*, 951
    - *Mycoplasma pneumoniae* infection, 1026
    - *Naegleria fowleri*, 1338
    - *Neisseria gonorrhoeae* infections, 763–764
    - *Rhodococcus equi* infections, 787
    - *Salmonella* infections, 841, 841*t*
    - *Shigella* infections, 845, 845*t*
    - *Ureaplasma urealyticum*, 1032
    - urethritis, 359
- Azole antifungal agents, 1235, 1236*t*, 1532–1533, 1532*t*
  - for *Blastomyces dermatitidis* (blastomycosis), 1273
  - for *Histoplasma capsulatum*, 1264–1265
  - for infections in hematopoietic stem cell transplant recipients, 577
  - for systemic infections, 1536–1539, Fluconazole, Itraconazole, Ketoconazole, Miconazole
- Aztreonam, 1516
  - for cystic fibrosis, 650
  - dosage for, 1490*t*–1498*t*, 1527*t*–1531*t*
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*

B

B cells, Blymphocytes
B lymphocytes, 89–92, 90*f*
  activated, 618
  antibody synthesis of, 618, 618*f*
  in common variable immunodeficiency disorder, 621
  deficiency
    in pneumonia, 257, 257*t*
    SCID, Severe combined immunodeficiency (SCID)
  development of, 618
  EBV infection and, 1089
  HIV infection and, 675
  Ig isotype expression and, 618
  immunopathologic consequences of HIV-1 infection on, 666*b*–667*b*
  signaling of, via CD40, 622
B virus, Herpes B virus (herpes simiae)
Babesia divergens, 1298
Babesia duncani, 1298–1299
Babesia microti, 1298
  asplenia from, 646
  clinical manifestations of, 1299, 1300*t*
  epidemiology of, 1299
  laboratory findings and diagnosis of, 1300, 1301*t*
Babesia species (babesiosis), 543*t*, 1298–1303, 1302*b*
  agents, vectors, and geographic distribution of, 543*t*
  Borrelia burgdorferi infection with, 1299
  clinical and laboratory manifestations of, 544*t*–545*t*
  clinical manifestations of, 1299, 1300*t*

- description of, 1298–1299
- diagnosis of, 1433
- epidemiology of, 1299, 1300*f*, 1302*b*
- in immunocompromised hosts, 1298–1300
- laboratory findings and diagnosis of, 1300, 1301*f*, 1301*t*, 1302*b*
  - *Plasmodium* infections *versus*, 1301*t*
- lymphocytosis from, 1453–1454
- microbiology of, 1302*b*
- prevention of, 1302
- treatment for, 1300–1302, 1302*b*, 1302*t*

Babesia venatorum, 1299

BabyBIG, 1004

Bacillary angiomatosis, *Bartonella henselae; Bartonella quintana*

Bacillary dysentery, *Shigella dysenteriae* type 1

Bacillary peliosis, *Bartonella henselae; Bartonella quintana*

Bacille Calmette-Guérin (BCG), Calmette-Guérin bacillus (BCG) vaccine

Bacilli, 690
- anaerobic Gram-negative, Anaerobic Gram-negative bacilli (AGNB)
- anaerobic Gram-positive nonsporulating, 1019–1022, *Actinomyces*
- Gram-negative, Gram-negative bacilli
- Gram-positive, Gram-positive bacilli

Bacillus alvei, 772–773

Bacillus anthracis (anthrax), 437*t*, 441, 770–772, 772*b*
- cutaneous anthrax, 441, 442*f*, 770
- gastrointestinal disease from, 771
- inhalational anthrax, 770–771

- postexposure prophylaxis of, 771

Bacillus brevis, 772–773

Bacillus cereus, 772, 1010
- endophthalmitis from, 514
- foodborne disease from, 398
- toxins in, 377

Bacillus circulans, 772–773

Bacillus coagulans, 772–773

Bacillus idriensis, 772–773

Bacillus infantis, 772–773

Bacillus laterosporus, 772–773

Bacillus licheniformis, 772–773

Bacillus macerans, 772–773

Bacillus pumilus, 772–773

Bacillus sphaericus, 772–773

Bacillus subtilis, 772–773

Bacillus thuringiensis, 772–773

Bacitracin
- resistance, of groups C and G streptococci, 736
- treatment for, eye infections, 1542*t*–1543*t*

Bacitracin disk test, 205

Back pain, 188–190
- causes of, 189*b*
- diseases associated with, 189*t*
- in diskitis, 494–495

BacT/Alert systems, 1424

BACTEC 460TB radiometric system, 1431

Bacteremia
  Bacillus cereus infections causing, 772
  Borrelia infection causing, 986
  in burn patients, 529–530
  catheter-associated, 586–587
  Corynebacterium species causing, 778*t*–780*t*
  endocarditis pathogenesis and, 262
  Haemophilus influenzae causing, 929
  Kingella kingae and, 946–947
  Listeria monocytogenes causing, 783–784
  in pneumonia, 238
  Pseudomonas aeruginosa causing, 868*t*
  rate after various procedures, 262, 263*t*
  Shigella causing, 844
  Streptococcus agalactiae (Group B *Streptococcus*) and, 724
  Streptococcus pneumoniae and, 4*f*
  viridans streptococci causing, 734, Bloodstream infections (BSIs), Septicemia
Bacteria
  adherence, in urinary tract infections, 343
  cell wall, 690*f*
    structure of, 690*f*
  cell wall-deficient, isolation of, 1425
  classification of, 690–692
  colonization by, Colonization; individual bacteria
  exanthems from, 446*b*
  fastidious, in antimicrobial susceptibility testing, 1431
  genome of, 692

identification
by molecular techniques, 691–692
by phenotypic characteristics, 690–691
laboratory diagnosis of, 1422–1431
normal flora, Flora, normal
obligate intracellular of, 690
outer membrane of, 690
phylogenetic tree of, 691, 691*f*
retinitis from, 510
skin infections from, 586*t*, 587
species, 690
translocation of, burn wounds, 529
Bacterial infections
corticosteroid use for, 657
generalized lymphadenopathy from, 131–133
in neonate see Neonatal infections, *see also individual infections*
Bacterial tracheitis, 214–215
clinical manifestations and differential diagnosis of, 214, 215*f*
complications and prognosis of, 215
, epidemiology and pathogenesis of, 214
etiologic agents of, 214
management of, 214–215
Bacterial vaginosis (BV)
Gardnerella vaginalis causing, 787
pelvic inflammatory disease and, 367
vaginitis and, 359*f*, 362
Bactericidal permeability-increasing protein, recombinant, for meningococcal disease, 754

Bacteriocins, 436

Bacteriuria

  covert or asymptomatic, 347

  risk factor for, 343–344

Bacteroidaceae, 988

Bacteroides, 1012–1014

  antimicrobial resistance of

    metronidazole, 1468*t*, 1473

    trimethoprim-sulfamethoxazole, 1474

  Clostridium botulinum inhibition to, 1000

  isolation of, media used for, 1425*t*

  secondary bacterial peritonitis from, 425

Bacteroides corrodens, 859

Bacteroides fragilis, 1012

  appendicitis from, 429

  normal flora of, 994*t*

Bacteroides melaninogenicus, 988

Bacteroides melaninogenicus group, 1012

Bacteroides ureolyticus, 859

Baerman technique, 1432

Bairnsdale ulcer, 808

Baker cyst, in *Borrelia burgdorferi* (Lyme disease), 983, 983*f*

Balamuthia mandrillaris

  acute disseminated encephalomyelitis from, 325–326

  granulomatous amebic encephalitis from, 312, 315, 316*f*

  laboratory testing of, 318*t*–321*t*

Balanitis, *Gardnerella vaginalis* and, 788

Balanoposthitis, 356

Balantidium coli, 1303–1305
  clinical manifestations of, 1303, 1305*f*
  description of, 1303, 1304*f*
  diagnosis of, 1303
  epidemiology of, 1303
  life cycle of, 1303, 1304*f*
  prevention of, 1303–1305
  treatment for, 1303–1305
  in water supply, 390
Balloon degeneration, in HSV infections, 1056
Barmah Forest virus, 1127
  arthritis from, 491
Bartonella, 454
  in blood, 1425
  in respiratory tract, 1427
  species of, 968
Bartonella bacilliformis, 881, 968
  epidemiology of, 882
Bartonella henselae, 881
  abdominal computed tomography for, 883*f*–884*f*
  abdominal lymphadenopathy from, 157
  axillary lymphadenopathy from, 883*f*–884*f*
  bacillary angiomatosis from, 882
  bacillary peliosis from, 882
  bacteremia from, 882
  cat-scratch disease, 881–886, 885*b*
    clinical findings of, 883*f*–884*f*
    clinical manifestations of, 882

        - complications, sequelae, and prognosis from, 885
        - epidemiology of, 881–882
        - laboratory findings and diagnosis of, 882–885
        - lymphadenitis from, 882
        - Parinaud oculoglandular syndrome from, 882
        - pathogen, description of, 881–882
        - prevention of, 885
        - systemic, 882
        - treatment of, 885
    - chronic fatigue syndrome from, 1038*b*
    - cross-reactions with, *Yersinia enterocolitica*, 847
    - encephalitis from, 312
    - encephalopathy from, 180
    - epidemiology of, 881
    - erythema nodosum from, 883*f*–884*f*
    - generalized lymphadenopathy from, 131
    - granulomatous conjunctivitis from, 883*f*–884*f*
    - granulomatous hepatitis from, 417
    - histologic specimen, of excised neck mass, 883*f*–884*f*
    - infections from, 130, 882
    - laboratory testing of, 318*t*–321*t*
    - lymphadenopathy from, 883*f*–884*f*
        - preauricular, 883*f*–884*f*
    - mediastinal lymphadenopathy from, 151–152
    - osteomyelitis from, 480
    - papular lesion from, 883*f*–884*f*
    - superficial necrotizing mass, in neck, 883*f*–884*f*
- *Bartonella quintana*, 881

- bacillary angiomatosis from, 882
- bacillary peliosis from, 882
- bacteremia from, 882
- epidemiology of, 882
- genome size of, 691
- infections from, 882

Bartonellaceae, 968

Bartonellosis, *Bartonella bacilliformis*

Basal cell(s), HPV infection in, 1101–1102

Basal ganglia, calcification, in HIV infection, 670–671, 671*f*

Basidiobolus, 1247–1248

Basilar artery migraine, 181*t*, 182

Basilar skull fracture, 525–526

- pathogens and recommended prophylaxis following, 523*t*

Basophilia, 1457

Basophils, 629, 1457

Bat bites, rabies and, 311*f*

Baylisascaris procyonis

- acute disseminated encephalomyelitis from, 325–326
- chronic meningitis from, 292–293, 292*t*
- clinical features of, 1383
- CNS migration of, 341
- diagnosis of, 1383
- encephalitis from, 305–310, 316*f*
- eosinophilic meningitis from, 339, 340*t*, 341, 1383
- laboratory testing of, 318*t*–321*t*
- life cycle of, 1382, 1384*f*
- ocular larva migrans from, 1381–1384

  - optic neuritis from, 325
  - treatment of, 342, 1383
- BC-selective agar, 1424*t*
- BCG vaccine, Calmette-Guérin bacillus (BCG) vaccine
- Beau lines, in Kawasaki disease, 1033–1035
- Beck triad, 275
- Bed nets, in *Plasmodium* infection prevention, 1349
- Bejel, 969
  - endemic syphilis, 977
- Bell palsy, 323–324, Facial nerve palsy
- Benzimidazoles
  - for *Ascaris lumbricoides* infections, 1375
  - for *Echinococcus granulosus* infections, 1407
  - for *Enterobius vermicularis* infections, 1379
  - for hookworm infections, 1377
  - for intestinal nematode infections, 1374
  - for *Trichuris trichiura* infections, 1378, Albendazole, Mebendazole, Thiabendazole
- Benznidazole, 1568
  - adverse effects of, 1583
  - for *Trypanosoma cruzi* infection, 1572
- Benzyl alcohol
  - lotion, treatment for, lice infestation, 1572
  - for pediculosis treatment, 1296
- Benzyl benzoate, for scabies treatment, 1298
- *Bergeyella*, 857–858
- *Bergeyella zoohelcum*, 858
  - bite wound infection from, 532

Besifloxacin, treatment for, eye infections, 1542*t*–1543*t*

Betaherpesvirinae, 1055, 1055*t*

Bethesda system, 1101–1102, 1102*t*

Bias, 4, 9

- affecting validity of study, 4
- diagnosis of, 4–5
- estimation of exposure in, 4–5
- impact of, 4–5
- selection for case-control studies, 4–5
- sources of, 4*b*
- types of, 5

Bifidobacterium, 1022

- classification of, 988
- normal flora of, 988

Bile, culture for, 422

Bile acid metabolism, disorders of, 413

Bile ducts

- fascioliasis and, 1415
- paucity of, 412

Biliary atresia, 412, 421

Biliary colic, migration and radiation of pain of, 173

Biliary dyskinesia, in acute abdominal pain, 175

Biliary stones, 421

Biliary tract disease

- *Cryptosporidium* infections causing, 1307
- intra-abdominal abscesses causing, 433

Bilirubin, in intra-abdominal abscesses, 433

Bioavailability, 1478–1479

Biofilm, 193
  for coagulase-negative staphylococci, 707–708
  for *Pseudomonas aeruginosa*, 867
Biologic response modifier therapy, 656*b*
  FDA-approved, 652*t*
  immunizations
    after biologic response modifier discontinuation, 654
    during biologic response modifier therapy, 654
    of immunocompetent household contacts, 654
    before initiation of biologic response modifier therapy, 653–654
    management of, 653–654
  indications for, 652*t*
  infections related to, 651–656
    endemic mycoses and other fungi as, 653
    hepatitis B as, 653
    herpes simplex as, 653
    human immunodeficiency virus as, 653
    nontuberculous *Mycobacterium* species as, 653
    Pneumocystis jirovecii and rituximab treatment in, 653
    rituximab-associated neutropenia as, 651–652
    serious infections, overall rate of, 651
    tuberculosis as, 652–653
    varicella-zoster virus as, 653
  initiation, during use, and after discontinuation of, consideration for patients in, 653–656
    general precautions in, 653
    screening/immunizations for, 654*t*
Biopsy

  - brain, Brain biopsy
  - duodenal, for *Giardia intestinalis*, 1319
  - intestinal, 391–392
  - liver, for HCV infection, 1140
  - small bowel, for *Cyclospora* or *Cystoisospora*, 1322
  - tissue, transport systems and media inoculated routinely in, 1423*t*
- Bioterrorism, biological agents used for, 770
- *Bipolaris*, 1245–1247
- Birds
  - avian influenza (H5N1 strain), 1188, Avian influenza (H5N1 strain)
  - *Toxocara* egg dispersal in, 1384
- Birth history, of recurrent infections, 615
- Bites, infection after, 532–537
  - bat bites, 533–534
  - cat bites, 533*t*
    - abscess, 534*f*

Brain abscess
  Aspergillus causing, 329, 1239
  Bacillus cereus causing, 772
  in burn patients, 529–530
  Candida causing, 329
  Citrobacter causing, 827–828, 828*f*
  clinical manifestations of, 331–332, 333*t*
    in relation to site of, 332*b*
  complications and prognosis of, 338
  CT for, 334–335, 334*f*–335*f*
  differential diagnosis of, 333
  Entamoeba histolytica causing, 329
  epidemiology of, 330–331
  etiology of, 329–330, 329*t*
    organisms by site of, 330*t*
    uncommon pathogens in, 330*t*
  fungal, 329
  Gram-negative bacteria causing, 329
  laboratory findings and diagnosis of, 333–335
  Listeria monocytogenes causing, 329, 784
  management of, 335–338
    antibiotics for, 336
    drainage for, 834
    empiric therapy for, 338*t*
  mortality of, 338
  MRI for, 334, 334*f*
  Mycobacterium tuberculosis causing, 329
  Nocardia causing, 329

  nuchal rigidity in, 179
  pathogenesis of, 331, 331*b*
    contiguous spread, 331
    hematogenous spread, 329, 331
  Proteus, Providencia, Morganella infections and, 834
  Staphylococcus aureus causing, 329
  stereotactic aspiration for, 336
  Streptococcus intermedius and *Eikenella corrodens* causing, 735*f*
  Toxoplasma gondii causing, 329, 1356
  transport systems and media inoculated routinely in, 1423*t*
  Ureaplasma urealyticum causing, 1031
  viridans streptococci causing, 734
Brain biopsy, for encephalitis, 321
Brainstem encephalitis
  enterovirus causing, 1210
  Listeria monocytogenes causing, 784
Brainstem glioma, ataxia in, 182
Branched-chain DNA (bDNA) assay, for virus detection, 1435–1436
Branchial cleft cysts, sinuses and, 143
Brazilian purpuric fever (BPF), 501–502
Breast abscess, 468–469
  coagulase-negative staphylococci (CoNS) causing, 710
  Staphylococcus aureus causing, 468–469
Breastfeeding/breastmilk
  in HCV, 1136, 1141
  as infant botulism risk, 1001
  infection protection/prevention from
    astrovirus, 1225

rotavirus prevention, 1125
transmission of HIV, interventions on, 663–664
Vibrio cholerae protection and, 878
Breath, malodorous, acute bacterial sinusitis and, 231
Brevundimonas, 857
Brevundimonas diminuta, 857
Brevundimonas vesicularis, 857
Brill-Zinsser disease, *Rickettsia prowazekii*
Brodie abscess, 480
Bronchial breath sounds, 171
Bronchiectasis, 648
mediastinal lymphadenopathy from, 152
persistent pneumonia with, 251, 251*f*
Bronchiolitis, 234–237
acute, 236
Bordetella pertussis causing, 234
clinical manifestations of, 236
complications of, 237
in congenital heart disease, 236
course of, 236–237
diagnosis of, 236
differential diagnosis of, 236
epidemiology of, 234–236
etiologic agents of, 234, 235*t*
hospitalization rates of, 234
management of, 236–237
Mycoplasma pneumoniae causing, 234
parainfluenza viruses causing, 1155

  - pathogenesis and pathologic findings of, 236
  - prevention of, 237
  - prognosis of, 237
  - respiratory syncytial virus (RSV) causing, 234
  - risk factors for, 236
  - sequelae of, 237
  - therapies for, 237
- Bronchiolitis obliterans, 254
- Bronchiolitis obliterans organizing pneumonia, 254
- Bronchitis, acute, 215

Bronchoalveolar lavage (BAL)
  for *Aspergillus* infections, 1242
  for persistent pneumonia, 253
  for *Pneumocystis jirovecii (carinii)* detection, 1267
  for pneumonia in HIV infection, 677
Bronchodilator therapy
  for bronchiolitis, 237
  for ciliary dysfunction, 648
  for human metapneumovirus, 1167
Bronchogenic cysts, persistent pneumonia and, 252
Bronchopleural fistula, 245–246
Bronchopneumonia, 240–241
  influenza causing, 1184, Pneumonia
Bronchoscopy
  for CMV pneumonia, 260
  for persistent pneumonia, 253
Bronchus-associated lymphoid tissue (BALT), 258
Brood capsules, *Echinococcus granulosus* and, 1404, 1406*f*
Broth microdilution assay, 1428
Brucella abortus
  biovars of, 886*t*
  cross-reactions with, *Yersinia enterocolitica*, 847
  enteric illnesses from, 399*t*–405*t*
  pneumonia from, 240*t*
  routes of acquisition of, 887*t*
Brucella abortus strain 19, 888
Brucella canis

- biovars of, 886*t*
- routes of acquisition of, 887*t*

Brucella melitensis
- biovars of, 886*t*
- epidemiology of, 886
- routes of acquisition of, 887*t*
- strain Rev-1, 888

Brucella neotomae, biovars of, 886*t*

Brucella ovis, 886*t*

Brucella species (brucellosis), 454, 886–889, 889*b*
- chronic meningitis from, 289–290, 292*t*
- clinical manifestations of, 887–888, 887*t*
- endocarditis from, 888
- epidemiology of, 886–887
- hepatic granulomas from, 888
- isolation of, media used for, 1425*t*
- joint infections from, 487
- laboratory findings and diagnosis of, 888
  - in blood, 1425
- laboratory testing from, 318*t*–321*t*
- meningitis from, 887–888
- organ systems of involvement in, 887–888
- pathogen and pathogenesis of, 886
- pregnancy and, 886–888
- prevention of, 888
- routes of acquisition of, 887*t*
- treatment and outcome of, 888, 889*t*

Brucella suis

biovars of, 886*t*
routes of acquisition of, 887*t*
Brucellosis, *Brucella* species (brucellosis)
Brudzinski sign, 281, 303, 1208
Brugia malayi, 1293*t*, 1388*t*
Brugia timori, 1388*t*
Bruton agammaglobulinemia tyrosine kinase gene *(BTK)*, 620
Bubo(es), *Yersinia pestis* causing, 849
Bubonic plague, 849
Bull-neck appearance, 204
Bullae, 437*t*, 447–450
clinical manifestations of, 448–450, 449*t*
etiology of, 448–450
flaccid, infections associated with, 449
hemorrhagic, 112, 454–455
tense, infection associated with, 449–450
Bullous impetigo, 437, 438*f*
Bull's eye lesions, 591
Bunyaviridae, 1045*t*, 1132–1135
clinical manifestations of, 1134–1135
description of, 1132
diseases in, clinical characteristics of, 1134*t*
epidemiology of, 1132–1134
infections, 1046*t*
laboratory findings and diagnosis of, 1135
prevention of, 1135
taxonomy and epidemiologic characteristics of, 1133*t*
treatment for, 1135

Burkholderia, 871

Burkholderia cenocepacia, lung transplantation and, 569

Burkholderia cepacia

- cystic fibrosis from, 254
- isolation of, 1427
  - media used for, 1425*t*

Burkholderia cepacia complex, 871–872, 871*b*, 871*t*

- epidemiology of, 872
- virulence and pathogenesis of, 872

Burkholderia gladioli, 871*t*, 873

Burkholderia mallei, 871*t*, 873

Burkholderia pseudomallei, 871*t*, 872

Burkitt lymphoma, 195*t*

Burns

- infections after, 527–532
  - bacteremia, 529–530
  - catheter-related, 530
  - central nervous system infections, 530
  - intra-abdominal, 530
  - *Pseudomonas aeruginosa*, 528–529, 868*t*
  - respiratory tract, 529
  - urinary tract, 530
  - viral, 530, Burns, wound infection
- pharmacokinetics of, 1482, 1483*t*
- prevention of, 531
- total body surface area of, 527
- , treatment for, 530–531, 531*t*, 1546–1550, 1549*t*–1550*t*
  - debridement, 530

    - dressing, 531
    - outpatient management, 531
    - systemic antimicrobial, 530
    - topical antimicrobials, 530, 531*t*
  - wound infection, 527–529
    - anaerobic, 529
    - biopsy findings of, 528*b*
    - blood supply affecting, 528
    - clinical characteristics of, 528*b*
    - colonization by pathogens, 528
    - debridement, 530
    - early infections of, 529
    - fungal, 529
    - group A *Streptococcus* (GAS), 528
    - host factors, 528
    - immunologic dysfunction in, 528*t*
    - later infections of, 529
    - local signs of, 528*b*
    - organism number effect, 529
    - prophylactic antibiotics for, 531
    - *Pseudomonas aeruginosa*, 528–529
    - *Staphylococcus aureus*, 528–529
    - systemic signs of, 528*b*
    - temporary membranes, 530
    - tetanus and, 529
    - wound factors, 528
  - wound sepsis from, *Pseudomonas aeruginosa* causing, 868*t*
- Burow solution

for ear infections, 1545*t*

for tinea cruris, 1285

Buruli ulcer, 808

Butenafine, for superficial infection, 1532*t*, 1533

Buttiauxella, 829

C

C-reactive protein (CRP)

for bacterial infections, in neonate, 552

clinical usefulness of, 1449–1450

for focal suppurative infections of the nervous system, 333–334

for infected neonate, 548

for Kawasaki disease, 114

low, 1449–1450

for osteomyelitis, 481

for pelvic or scrotal pain syndrome, 352

physiology and measurement of, 1449

for pyogenic arthritis, 488

for transient synovitis, 496

C1q deficiency, 627

C1r or C1s deficiency, 627

C2 deficiency, 627

C3, 624

activation of, 625

deficiency, 627

in *Mycoplasma pneumoniae*, 1025

C4, deficiency, 627

in recurrent meningitis, 296

C5, deficiency, 627

  in recurrent meningitis, 296

C6, deficiency, 627

  in recurrent meningitis, 296

C7 deficiency, 627

  in recurrent meningitis, 296

C8 deficiency, 627

C9 deficiency, 627

Calabar swellings, 1392

Calcifications

  intracranial, congenital toxoplasmosis causing, 1355, 1357

  neurocysticercosis *(Taenia solium)* and, 1400*f*, 1401, 1402*t*

Calcium, *Entamoeba histolytica* infection and, 1312

Calcofluor white stain, 1431

Caliciviridae, 1045*t*, 1221

  infections, 1046*t*

  optimal tests for, 1437*t*–1440*t*

Caliciviruses, 383, 1221–1224

  clinical manifestations of, 1223

  enteric illnesses from, 399*t*–405*t*

  epidemiology of, 1221–1223, 1223*f*

  gastroenteritis from, 383

  laboratory findings and diagnosis of, 1223

  pathogens and pathogenesis of, 1221

  prevention of, 1223

  treatment for, 1223

California [La Crosse] virus, diagnosis/detection of, 1437*t*–1440*t*, 1445

California serogroup viruses, 1133–1135, 1134*t*

Calmette-Guérin bacillus (BCG) vaccine, 83, 805–806

- for subacute or chronic unilateral lymphadenitis, 142

Calymmatobacterium granulomatis, *Klebsiella (Calymmatobacterium) granulomatis* (donovanosis)

Campylobacter, 454, 899, 903–904, 904*t*, 1010

- bloodstream infection from, 901
- clinical manifestations of, 900–901
- description of, 899, 899*t*
- diagnosis of, 901
- enteritis, 900
- epidemiology of, 899
- foodborne disease from, 398
- immune-mediated complications of, 901
- immunity to, 900
- isolation of, media used for, 1425*t*
- localized extraintestinal infections from, 901
- pathogenesis of, 900, 900*t*
- perinatal infections from, 901
- phylogenetic trees of, 903
- prevention of, 902
- treatment of, 901–902, 902*t*

Campylobacter agar, 1424*t*

Campylobacter coli, 899–903, 899*t*, 902*b*, 904*t*

Campylobacter concisus, 899*t*, 904

- diarrhea from, 904*t*

Campylobacter curvus, 899*t*, 904, 904*t*

Campylobacter fetus, 903, 904*t*

  - bloodstream infection from, 903
  - clinical manifestations of, 903
  - fever from, 903
  - management of, 903
  - microbiology and epidemiology of, 903
  - mortality of, 903
  - perinatal infections from, 903
  - in pregnancy, 903
  - virulence factor of, 903
- *Campylobacter fetus* subsp. *fetus*, 899*t*, 903
  - microbiology and epidemiology of, 903
- *Campylobacter fetus* subsp. *venerealis*, 903
- *Campylobacter gracilis*, 904, 904*t*
- *Campylobacter helveticus*, 904*t*
- *Campylobacter hyointestinalis*, 899*t*, 904, 904*t*
- *Campylobacter jejuni*, 899–903, 902*b*, 904*t*
  - abdominal pain from, 175
  - epidemiology of, 899
  - foodborne disease from, 399*t*–405*t*, 406
  - Guillain-Barré syndrome from, 326
  - inflammatory enteritis from, 389, 389*t*
  - pathogenesis of, 900
  - phylogenetic tree of, 903
  - reservoir for, 389
  - traveler's diarrhea from, 380
  - *Trichuris trichiura* synergy and, 1378
- *Campylobacter jejuni* subsp. *doylei*, 899*t*
- *Campylobacter jejuni* subsp. *jejuni*, 899*t*

Campylobacter lari, 899*t*, 904, 904*t*

Campylobacter pyloridis, *Helicobacter pylori*

Campylobacter rectus, 899*t*, 904, 904*t*

Campylobacter showae, 904, 904*t*

Campylobacter sputorum, 904, 904*t*

Campylobacter sputorum subsp. *sputorum*, 899*t*

Campylobacter upsaliensis, 899*t*, 904, 904*t*

- clinical manifestations of, 904
- diarrhea from, 904
- epidemiology of, 904
- microbiology of, 904
- phylogenetic tree and, 903
- septicemia from, 904
- treatment of, 904

Campylobacteriosis, *Campylobacter*

Cancer

- infections in children with, 586–592
  - catheter-related and soft-tissue, 586–587
  - central nervous system infections of, 591
  - cystitis, 591
  - diagnosis and management of specific clinical syndromes of, 586–591
  - gastrointestinal tract infections and, 590–591
  - intra-abdominal infections of, 590–591
  - mucositis and esophagitis of, 590
  - osteoarticular of, 591
  - pulmonary infections of, 587–589, 588*t*
  - skin, 587

varicella complications and, 1068
Candida, 1231–1237, 1237*b*
antigen detection of, 1235
arthritis from, 492
blood culture of, 1235
brain abscess from, 329
burn wound infections from, 529
chronic disseminated candidiasis, 591
chronic fatigue syndrome from, 1038*b*
clinical manifestations of, 1232–1235
diskitis from, 493
DNA polymerase chain reaction for, 1235
epidemiology of, 1231–1232
esophageal candidiasis, in HIV infection, 679
fungal metabolites of, 1235
heart transplantation and, 569
hospital-associated infection from, 565
infections in hematopoietic stem cell transplant recipients, 574–575
inflammatory enteritis from, 392
intravascular catheter-related infections from, 605
invasive infections from, 1232–1235
laboratory findings and diagnosis of, 1235
liver transplantation and, 569
oral infections, in HIV infection, 679
osteomyelitis from, 485
pneumonia, cancer and, 588
prevention of, 1237

- renal transplantation and, 569
- risk factors increasing colonization of, 1236
- risk factors that disrupt or impair immune function from, 1236–1237
- routine tests for, 1235
- serologic testing for, 1235
- superficial and mucosal infections from, 1232
- treatment of, 1235–1236, 1236*t*
- vulvovaginitis from, 360, *Candida albicans*

Candida albicans
- chronic meningitis from, 291
- diaper dermatitis from, 355–356
- endophthalmitis from, 514
- genital dermatosis from, 355–356
- identification of, 1431
- infective keratitis from, 507
- intertrigo from, 438
- urinary tract infections from, 348
- vaginitis from, 362–365, *Candida*

Candida dubliniensis, 1232

Candida glabrata, 1232
- genital dermatosis from, 355–356
- urinary tract infections from, 348

Candida guilliermondii, 1232

Candida kefyr, 1232

Candida lusitaniae, 1232

Candida parapsilosis, 1231–1232

Candida tropicalis, 1232

Candidemia, 1232–1233, 1234*f*
Candidiasis, 1232–1233
  vaginitis and, 362
Cannula, indwelling, infections, in transplant recipients, 567–568
Capnocytophaga
  biogroup dysgenic fermenter [DF]-1 and, 905
  CDC biogroup DF-2 and, 905
  species, 905–906
Capnocytophaga canimorsus, 905
  animal bite infection from, 532
  dog-bite wound and, 905
Capnocytophaga cynodegmi, 905
Capnocytophaga gingivalis, 905
Capnocytophaga granulosa, 905
Capnocytophaga haemolytica, 905
Capnocytophaga sputigena, 905
Capreomycin, for childhood TB, 802*t*
, Capsule, of *Staphylococcus aureus*, 693
Carbapenem(s), 1515–1516
  dosage for, 1527*t*–1531*t*
    impaired renal function, 1490*t*–1498*t*
  pharmacokinetics of, 1499*t*–1505*t*
  resistance to, 1470
    detection of, 1476, 1476*f*
  spectrum of activity of, 1506*t*–1511*t*
  structure of, 1512*f*
  treatment for
    sepsis, 100–101

    - for *Serratia* infections, 836
- Carbapenemases
  - in antimicrobial susceptibility testing, 1430
  - for *Serratia* infections, 836
- Carbaryl, for pediculosis treatment, 1296
- Carbenicillin
  - for eye infections, 1543*t*
  - spectrum of activity of, 1506*t*–1511*t*
- Carbohydrate metabolism disorders
  - acute hepatitis and, 413
  - chronic hepatitis and, 416
- Carbuncle, 437*t*, 440–441
- Card agglutination test for trypanosomiasis (CATT), 1368
- Cardiac abnormalities
  - congenital rubella syndrome in, 1145
  - persistent or recurrent pneumonia in, 255
- Cardiac arrhythmias, *Corynebacterium diphtheriae* causing, 775
- Cardiac disease
  - adenoviruses causing, 1098*t*
  - HIV infection causing, 673
  - with *Mycoplasma pneumoniae*, 1024*t*
- Cardiac infections, adenoviruses causing, 1099
- Cardiac insufficiency, in fetus and neonate, viral infections causing, 558–559
- Cardiac muscle disease, enterovirus infections causing, 1210
- Cardiac surgery
  - infection chemoprophylaxis in, 75–76
  - surgical site infections in

    - clinical manifestations and laboratory diagnosis of, 599
    - epidemiology and pathogenesis of, 597–598
    - management and outcome of, 599
    - prevention of, 600
- Cardiac tamponade, 274
- *Cardiobacterium hominis*, 968
  - endocarditis from, 968
- Cardiomyopathy
  - chronic dilated, enterovirus infections causing, 1210
  - *Corynebacterium diphtheriae* causing, 775
  - HIV infection causing, 673
- Cardiovascular disturbances, in *Trypanosoma cruzi* infections, 1371
- Cardiovascular physiology, in chronic fatigue syndrome, 1039
- Cardiovascular shock, in meningococcal disease, 754
- Carditis
  - acute rheumatic fever and, 720
  - *Borrelia burgdorferi* (Lyme disease) causing, 982, 982*b*, 984*b*

    - prevention of, 606–607, 606*b*
    - *Staphylococcus aureus* and, 605
- Caulobacteraceae, 856
- Causal inference, 4–5
- Cavernous sinus thrombosis, 332
- CCR5, in human immunodeficiency virus, 1199
- CD4 molecule, in human immunodeficiency virus, 1198–1199
- CD4 receptor, HIV binding to, 683
- CD4⁺ T cells, Tlymphocytes, CD4+ (helper)
- CD8 T cells, Tlymphocytes, CD8
- CD21, EBV receptor and, 1089
- CD40 deficiency, 622
- CD40 ligand (CD40L), 641
  - deficiency, 618–620, 622
  - mutation of, 622
  - *Pneumocystis jirovecii (carinii)* pneumonia and, 1267
- CD45, 636
- CD46 protein, 502

CD132, 636

Cecitis, neutropenic, cancer and, 590–591

Cedecea, 829–830

Cefaclor

  dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*

  pharmacokinetics of, 1499*t*–1505*t*

  spectrum of activity of, 1506*t*–1511*t*

Cefadroxil

  dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*

  pharmacokinetics of, 1499*t*–1505*t*

  spectrum of activity of, 1506*t*–1511*t*

Cefamandole, spectrum of activity of, 1506*t*–1511*t*

Cefazolin

  dosage for, 1490*t*–1498*t*, 1527*t*–1531*t*

  pharmacokinetics of, 1499*t*–1505*t*

  spectrum of activity of, 1506*t*–1511*t*

  for *Streptococcus agalactiae* (Group B *Streptococcus*) prevention, 727–728

  treatment for

    bacterial keratitis, 508

    dacryocystitis, 519

    endophthalmitis, 515

    eye infections, 1543*t*–1544*t*

Cefdinir

  dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*

  pharmacokinetics of, 1499*t*–1505*t*

  spectrum of activity of, 1506*t*–1511*t*

Cefepime

- for acute bacterial meningitis, 284
- dosage for, 1527*t*–1531*t*
  - impaired renal function, 1490*t*–1498*t*
- pharmacokinetics of, 1499*t*–1505*t*
- spectrum of activity of, 1506*t*–1511*t*

Cefixime
- dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*
- pharmacokinetics of, 1499*t*–1505*t*
- spectrum of activity of, 1506*t*–1511*t*
- treatment for
  - *E. coli* diarrheal infections, 818
  - *Neisseria gonorrhoeae* infections, 765
  - *Shigella* infections, 845, 845*t*
  - urinary tract infections, 345

Cefonicid, spectrum of activity of, 1506*t*–1511*t*

Cefoperazone
- pharmacokinetics of, 1499*t*–1505*t*
- spectrum of activity of, 1506*t*–1511*t*

Ceforanide, spectrum of activity of, 1506*t*–1511*t*

Cefotaxime, 740*t*, 741*f*
- dosage for, 1490*t*–1498*t*, 1527*t*–1531*t*
- pharmacokinetics of, 1499*t*–1505*t*
- spectrum of activity of, 1506*t*–1511*t*
- structure of, 1512*f*
- treatment for
  - acute bacterial meningitis, 283
  - acute bacterial sinusitis, 233
  - eye infections, 1544*t*

    - *Haemophilus influenzae*, 930
    - infants with fever without localizing signs, 117
    - *Leptospira* infections, 979–980
    - *Neisseria gonorrhoeae* infections, 764

Cefotetan
  - dosage for, 1527*t*–1530*t*
  - spectrum of activity of, 1506*t*–1511*t*

Cefoxitin
  - dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*
  - for *Neisseria gonorrhoeae* infection treatment, 764
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*

Cefpodoxime
  - dosing of, 1490*t*–1498*t*
  - for *Neisseria gonorrhoeae* infections, 764
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*

Cefpodoxime proxetil, dosage for, 1527*t*–1530*t*

Cefprozil
  - dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*
  - pharmacokinetics of, 1499*t*–1505*t*

Ceftaroline
  - dosage for, 1527*t*–1530*t*
    - impaired renal function, 1490*t*–1498*t*
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*

Ceftazidime
  - dosage for, 1527*t*–1531*t*

    - impaired renal function, 1490*t*–1498*t*
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*
  - treatment for
    - acute mastoiditis, 228–229
    - endophthalmitis, 515, 516*t*
- Ceftazidime-avibactam
  - dosage for, 1527*t*–1530*t*
  - spectrum of activity of, 1506*t*–1511*t*
- Ceftibuten
  - dosage for, 1527*t*–1530*t*
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*
- Ceftizoxime
  - for *Neisseria gonorrhoeae* infection treatment, 764–765
  - spectrum of activity of, 1506*t*–1511*t*
- Ceftolozane, pharmacokinetics of, 1499*t*–1505*t*
- Ceftolozane-tazobactam
  - dosage for, 1527*t*–1530*t*
  - spectrum of activity of, 1506*t*–1511*t*
- Ceftriaxone, 740*t*, 1515
  - adverse effect of, 284–285
  - dosage for, 1490*t*–1498*t*, 1527*t*–1531*t*
  - for *Neisseria meningitidis* infection prophylaxis, 756
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*
  - treatment for
    - acute bacterial meningitis, 283

    acute bacterial sinusitis, 233
    acute otitis media, 219
    Borrelia burgdorferi (Lyme disease), 984*b*
    brain abscess and subdural empyema, 338
    epididymitis, 371–372
    , *Haemophilus ducreyi*, 933
    Haemophilus influenzae, 930
    Haemophilus influenzae biogroup *aegyptius*, 932
    infants with fever without localizing signs, 117
    Neisseria gonorrhoeae infections, 499, 763–764
    Salmonella infections, 841, 841*t*
    Shigella infections, 845, 845*t*
Cefuroxime
  dosage for, 1490*t*–1498*t*, 1527*t*–1531*t*
  pharmacokinetics of, 1499*t*–1505*t*
  spectrum of activity of, 1506*t*–1511*t*
  treatment for
    acute bacterial sinusitis, 233
    Borrelia burgdorferi (Lyme disease), 984
Celiac disease, chronic hepatitis and, 416
Cell culture
  for HSV, 1440–1441
  virus isolation and, 1435
Cell-mediated immunity
  in acquired rubella, 1143
  in *Histoplasma capsulatum*, 1260
  in HSV infections, 1056
  infectious complications of, 635–643

in *Leishmania* (leishmaniasis), 1323–1324
in pneumonia, 240
predominant pathogens infecting children with, 580*t*
role in control of infections, 635–636, Tlymphocytes
Cell membrane-active antibiotics, 1517
Cell wall
of *Staphylococcus aureus*, 693, Bacteria, cell wall
Cell wall-active agents, 1511–1517, 1512*f*
with ribosomal active agents, combination of, antimicrobial combinations, 1466
Cellular immune defects, 255
Cellular immunity, parainfluenza viruses and, 1153
Cellulitis, 437*t*, 443–444, 444*f*
Aeromonas causing, 854
Capnocytophaga canimorsus causing, 905
causes of, 444*t*
facial, 443
Haemophilus influenzae type b (Hib) causing, 443, 928–929, 929*f*
lid, *Bacillus anthracis* causing, 519–520
limb pain from, 188
perianal, in cancer, 591
secondary infections in varicella, 1067
Staphylococcus aureus causing, 443, 696
Streptococcus pneumoniae causing, 442
trauma causing, 523
Trichophyton causing, 519–520
Cellulose tape method, 1432
Cellulosimicrobium funkei (Oerskovia xanthineolytica), 789

Cellulosimicrobium (Oerskovia) species, 789, 790*b*

CEM-15, 1199

Centers for Disease Control and Prevention (CDC), 914

  chronic fatigue syndrome, definition of, 1037–1038

  for diphtheria, 773

  in influenza immunization, 1187

  for judicious antimicrobial use, 1467

  in *Listeria monocytogenes* infection rates, 782

  Malaria Hotline of, 1347

Central line associated bloodstream infections (CLABSIs)

  in cancer, risk, antibiotics for, 586–587

  management of, 564–565, 564*f*

  sepsis, causes of, 98

Central nervous system (CNS)

  Acanthamoeba infections of, 1341

  complications, rubeola virus infection (measles) and, 1173

  in congenital rubella syndrome, 1145–1146

  human herpesvirus 6 and, 1083–1084

  involvement of, *Brucella* species (brucellosis), 887–888

  manifestations, of viral hemorrhagic fever, 1192, 1192*f*

Central nervous system devices, infections associated with, 609–610, 610*b*

Central nervous system function, *Plasmodium* infection in, 1343–1344

Central nervous system (CNS) infections, 558

  adenoviruses causing, 1098*t*

  anaerobic cocci causing, 1018

  Blastomyces dermatitidis (blastomycosis) causing, 1274

  - in burn patients, 530
  - cancer and, 591
  - enteroviruses causing, 1208–1211
  - HIV infection causing, 678–679, 678*f*
  - HSV causing, 1059, 1060*f*, 1063, 1063*t*
  - mumps virus causing, 1159
  - with *Mycoplasma pneumoniae*, 1024–1025, 1024*t*
  - *Pseudomonas aeruginosa* and, 868*t*, 870
- Central venous catheter (CVC)
  - for *Candida* infections, 1235
  - *Malassezia* infections and, 1251
- Central venous catheter (CVC)-related infections
  - in cancer, neutropenia and infections, 579
  - HSCT recipients and, 574
- Centrifugation, of specimens in viral infections, 1435
- Cephalexin
  - dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*
- Cephalosporin(s), 1515
  - with anti-MRSA activity, 1499*t*–1505*t*
  - antipseudomonal, 870
  - for bite wound infection, 536
  - dosage for, 1527*t*–1531*t*
    - impaired renal function, 1490*t*–1498*t*
  - first-generation, 1499*t*–1505*t*, 1515
  - fourth-generation, 1499*t*–1505*t*, 1515
  - pharmacokinetics of, 1499*t*–1505*t*

  resistance to, *Neisseria gonorrhoeae*, 761
  second-generation, 1499*t*–1505*t*, 1515
    for abdominal trauma related infections, 525
  spectrum of activity of, 1506*t*–1511*t*
  third-generation, 1499*t*–1505*t*, 1515
    for abdominal trauma related infections, 525
    for *Actinobacillus actinomycetemcomitans*, 967–968
    for acute bacterial meningitis, 284
    for *Haemophilus influenzae* infections, 930
    for meningococcal meningitis, 753–754
  treatment for
    bacterial keratitis, 508
    chronic mastoiditis, 230
    infants with fever without localizing signs, 117
    Neisseria gonorrhoeae infections, 763–764
Cephalosporin (nitrocefin) method, 1430
Cephalosporinase, for *Bacillus anthracis*, 771
Cephalothin, spectrum of activity of, 1506*t*–1511*t*
Cephapirin, spectrum of activity of, 1506*t*–1511*t*
Cephradine
  pharmacokinetics of, 1499*t*–1505*t*
  spectrum of activity of, 1506*t*–1511*t*
Cercariae, 1293, 1413
  of *Fasciola hepatica*, 1415
  from intestinal trematodes, 1412
Cerebellar abscesses
  etiology of, 329, Brain abscess
Cerebellar ataxia

  - acute, 325
  - in varicella, 1067
- Cerebellar dysfunction, ataxia from, 182
- Cerebellitis, 325
  - acute, 325
  - etiologies of, 323*t*
  - magnetic resonance image for, 325*f*
  - management of, 325
- Cerebral aspergillosis, 1239
- Cerebral edema
  - in encephalitis, 322
  - *Plasmodium* infections and, 1346–1347
- Cerebral paragonimiasis, 1417
- Cerebritis, 335
- Cerebrospinal fluid (CSF)
  - analysis/features in
    - *Acanthamoeba* infection, 1339–1340
    - *Borrelia* infections, 986
    - encephalitis, 317, 321–322
    - *Toxoplasma gondii* infection, 1356, 1358*b*
  - in cerebellitis, 325
  - in *Coccidioides immitis* (coccidioidomycosis), 1280
  - collection and processing of, 1422, 1423*t*
  - in congenital syphilis, 971
  - containing pseudocyst, 424–425
  - culture
    - for head trauma, 525
    - for HSV, 304

  - for *Neisseria meningitidis*, 753
- cytology, for meningitis diagnosis, 282
- in eosinophilia, 292–293, 341, Eosinophilia
- eosinophilic pleocytosis, 342
- in focal suppurative infections of the nervous system, 334
- glucose, in *Naegleria fowleri*, 1337
- *Haemophilus influenzae* capsular polysaccharide and, 929–930
- leak
  - clinical manifestations of, 298
  - diagnosis of, 298–299
  - head trauma and, 525
  - recurrent meningitis, 295
- in *Leptospira* infections, 979
- in lymphocytic pleocytosis, 289–290
- meningococcal antigen in, 753
- *Mycoplasma hominis* infection in, 1028
- *Mycoplasma pneumoniae* in, 1023
- in neutrophilic pleocytosis, 292
- otorrhea, in recurrent meningitis, 295, 299
- PCR, for HSV infections, 1440–1441
- pleocytosis, 334
  - in aseptic meningitis, 304
  - in *Ehrlichia* and *Anaplasma* infections, 921
  - in encephalitis, 321
  - enterovirus infections causing, 1208
  - VZV infections and, 1069
  - in X-linked agammaglobulinemia, 621
- predominant leukocytes in, 294*t*

  pressure, for *Naegleria fowleri*, 1337
  rhinorrhea, in recurrent meningitis, 295, 299
  specimen-specific isolation methods in, 1426
Cerebrospinal fluid (CSF) fistula, in recurrent meningitis, 296
Cerebrospinal fluid shunt, infection
  coagulase-negative staphylococci (CoNs) causing, 709–710
  Staphylococcus aureus causing, 701
Cerebrovascular event, infant botulism *versus*, 1003*t*
Cerumen, 223
Cervical cytology, 1103
Cervical ectopy, 368*f*
Cervical lymph node
  deep, 137
  superficial, 137, Lymph nodes
Cervical lymphadenitis, 136–148
  abscess drainage for, 148
  anaerobic Gram-negative bacilli causing, 1013
  complications of, 148
  epidemiology of, 136, 136*t*
  Haemophilus aphrophilus causing, 933–934
  initial therapy for, 147–148, 147*t*
  management of, 147–148, 147*t*
  surgical excision and long-term therapy for, 148
Cervical lymphadenopathy
  diagnostic approach to, 140*t*, 144–145, 145*t*–146*t*, 146*b*
  in Kawasaki disease, 1033
  lymph node biopsy for, 145
  needle aspiration for, 144–145

Cervicitis, 365–366, 366*t*
  gonococcal, 761
  mucopurulent, *Chlamydia trachomatis* and, 913
Cervicofacial syndrome, *Nocardia* species causing, 814
Cervix, *Trichomonas vaginalis* infections in, 1365
Cesarean delivery, HIV transmission and, 662–663
Cestodes, 1293, 1293*t*, 1397
  pseudophyllidean, 1394
CH50 assay, 299
Chagas disease, *Trypanosoma (Schizotrypanum) cruzi*
Chalazion, 518–519
  as blepharitis complication, 504
Chancre, primary syphilis causing, 970
Charcot-Leyden crystals, 1375, 1378
  phaeohyphomycosis and, 1246
CHARGE syndrome, 637
, Chédiak-Higashi syndrome, 105, 629–630, 635
  characteristics of, 629*t*
  clinical illness associated with, patterns of, 630*t*
  infectious complications of, 630*t*
  management of, 631–632
  pathogens associated with, 629*t*
  prevention of, 633, 633*t*
Chemokines, 87, 1450
  parainfluenza viruses and, 1152–1153
Chemoprophylaxis, 746
  after tympanostomy tube placement, 1545–1546
  antimicrobial, 71–79

  - benefits of, 71
  - in children, 71
  - definition, 71
  - general principles of, 71–72
  - in healthy children, 72–75, 72*t*–74*t*
    - sexually transmitted pathogens, 75
    - specific pathogens, 72–75
    - unusual pathogens, 73*t*–74*t*, 75
  - for pneumonia, in immunocompromised host, 261
  - in special situations and in children with conditions predisposing to infection, 75, 77*t*
    - asplenia, 76–77
    - rheumatic fever, 76, 77*t*
    - underlying immunocompromising conditions, 77

  of *P. skrjabini*, 1417

Cremasteric reflex, 371

Crimean-Congo hemorrhagic fever (CCHF)

  agents, vectors, and geographic distribution of, 543*t*

  clinical and laboratory manifestations of, 544*t*–545*t*

  clinical manifestations of, 1134, 1134*t*

  epidemiology of, 1133, 1133*t*

  treatment for, 1135

Cronobacter (Enterobacter sakazakii), 824–827

  enteric illnesses from, 399*t*–405*t*

  microbiology of, 824–825

  neonatal meningitis from, 825

  treatment for, 825–826

Cross-sectional studies, 3–4, 3*t*

Crotamiton

  adverse effects of, 1584

  for pediculosis treatment, 1296

  for scabies treatment, 1298, 1572

Croup, Laryngotracheitis (croup)

Cryopyrin-associated periodic syndrome (CAPS), 127–128

  cardinal clinical features of, 128

  course, treatment, and outcome of, 128

  epidemiology and etiology of, 127

Cryptococcus, 1255–1259, 1258*b*–1259*b*

  characteristics of, 1256*t*

  clinical manifestations of, 1256–1257

  CNS infection and, 1257
  diagnosis of, 1257
  epidemiology of, 1256
  in hyperimmunoglobulin M syndrome, 622
  in immunocompromised patients, 1256
  neurologic manifestations of, 1257
  pneumonitis, cancer and, 588
  prevention of infection, 1258
  pulmonary manifestations of, 1257
  refractory infection, 1258
  serotypes, 1255–1256, 1256*t*
  skin manifestations of, 1257
  treatment of infection for, 1257–1258
, *Cryptococcus gattii*, 1255–1256, 1257*f*
  characteristics of, 1256*t*
  diagnosis of, 1257
  epidemiology of, 1256
Cryptococcus neoformans, 330
  arthritis from, 492
  capsule and acapsular strains of, 1256–1257
  characteristics of, 1256*t*
  in CSF, 1257
  diagnosis of, 1257
  encephalitis from, 312
  eosinophilia from, 1456
  eosinophilic meningitis from, 340*t*, 342
  epidemiology of, 1256
  HIV infection and, 676

isolation of, 1431
pneumonia in cancer from, 588–589
pulmonary manifestations of, 1257
serotypes A and D of, 1255–1256
treatment of infections for, 1258
virulence of, 1256
Cryptosporidium, 1306–1308, 1308*b*
clinical manifestations of, 1307, 1308*b*
detection of, 1432
enteric illnesses from, 399*t*–405*t*
epidemiology of, 1306–1307
in HIV infection, 679
in hyperimmunoglobulin M syndrome, 622
inflammatory enteritis from, 392
laboratory diagnosis of, 1307, 1307*f*, 1308*b*
oocyst of, 1306
oocyst shedding in, 1307
outbreaks of, in childcare center, 1307
pathogen, 1306
prevention of, 1308
special considerations in, 1308
transmission of, 1307
treatment for, 1308
water contamination and, 1307
Cryptosporidium hominis, 1306
Cryptosporidium parvum, 1306, 1567
acute pancreatitis from, 419–420
in water supply, 390

Ctenocephalides felis, 959

CTX-M enzyme, in drug resistance, 1470

Culex species mosquitoes, 83

  Japanese encephalitis virus in, 1129

  West Nile virus in, 1130

Cullen sign, 175

Culture

  for adenoviruses, 1100

  for bile, 422

  blood, Blood cultures

  of *Francisella tularensis* (tularemia), 925

  for HSV infections, 1060–1062

  peritoneal, 395, *see also individual micro-organisms*

Culture media

  in antimicrobial susceptibility testing, 1428, 1428*t*

  for common microorganisms, 1425*t*

  commonly used, 1424*t*

  differential, 1422

  enriched, 1422

  for isolation, of common microorganisms, 1425*t*

  selective, 1422

  types of, 1422

Cumulative hazard, 3

Cumulative hazard curves, 4*f*

Cumulative incidence, 1

Cunninghamella, 1247–1248

Currant jelly stool, 176

Cutaneous adverse drug eruptions (CADEs), 445–447, 447*f*

Cutaneous amebiasis, 1314

Cutaneous candidiasis, congenital, 1232, 1233*f*

Cutaneous disease, *Coccidioides immitis* (coccidioidomycosis) and, 1279, 1279*f*

Cutaneous infections, HSV causing, 1058–1059, 1059*f*, 1063, 1063*t*

Cyanobacteria-like bodies, 1321

Cyanotic congenital heart disease (CCHD), focal suppurative infections of the nervous system and, 329

Cyclic neutropenia, 125–126
  cardinal clinical features of, 126
  course, treatment, and outcome of, 126
  epidemiology and etiology of, 125–126

Cyclooxygenase, expression of, increase, 93–94

Cycloserine, for childhood TB, 802*t*

Cyclospora cayetanensis
  description of, 1321
  detection of, 1432
  enteric illnesses from, 399*t*–405*t*
  epidemiology of, 1321
  foodborne disease from, 398

Cyclospora species, 1321–1322
  clinical manifestations of, 1321–1322
  description of, 1321
  epidemiology of, 1321
  laboratory findings and diagnosis of, 1322, 1322*f*
  pathogens of, 1321
  prevention of, 1322
  treatment of, 1322

Cyclosporine, treatment for, Kawasaki disease, 1036
Cyst(s)
  of *Balantioides coli*, 1303, 1304*f*
  bronchogenic, 252
  choledochal, 412
  of *Endolimax nana*, 1309, 1309*f*–1310*f*
  of *Entamoeba histolytica*, 1310–1312, 1311*f*
  of *Giardia intestinalis*, 1317
  intramuscular, *Taenia serialis* (coenurosis) causing, 1410
  midline sinuses and, 143
  Naegleria fowleri and, 1336, 1336*f*
  Taenia solium neurocysticercosis and, 1400*f*, 1401
  Toxoplasma gondii in, 1353
Cystic echinococcosis, *Echinococcus granulosus*
Cystic fibrosis, 648–651
  acute hepatitis and, 412
  allergic bronchopulmonary aspergillosis and, 1240
  Burkholderia cepacia infections causing, 871
  chronic hepatitis and, 416
  clinical manifestations of, 649
  diagnosis of, 254
  drug disposition in, 1481–1482
  epidemiology of, 648–649
  etiologic agents of, 648, 648*t*
  laboratory findings of, 649–650, 649*f*
  management of, 650
  pathogenesis of, 649
  prevention of, 650–651

Pseudomonas aeruginosa infections and, 868*t*, 1471, 1477–1478
recent advances in, 650
recurrent pneumonia and, 254
Stenotrophomonas maltophilia causing, 873–874
in transplant recipients, 567
Cystic hygroma, 143–144, 144*f*
Cysticercoids, of *Hymenolepis nana*, 1395
Cysticercosis, 1293, 1293*t*
chronic meningitis from, 292*t*, *Taenia solium;*, Tapeworms
Cystitis
acute hemorrhagic, adenovirus causing, 1100
cancer and, 591
hemorrhagic
BK virus and, 1106
in HSCT recipients, 575, 1106
severe hemorrhagic, 343
in solid organ transplant recipients, 570
Cystoisospora (cystoisosporiasis), 1321
epidemiology of, 1321
laboratory diagnosis of, 1322
Cystoisospora belli, 1321
epidemiology of, 1321
laboratory findings of, 1322, 1322*f*
Cytochrome P-450 (CYP)
drug-drug interactions of, 1484, 1485*t*
inhibition by itraconazole, 1536
“Cytokine storm”, 718
in hemophagocytic lymphohistiocytosis, 104

Cytokines, 1450
  in acute phase response, 1447
  in common colds, release of, 200
  induced by *Shigella*, 843
  in N*eisseria meningitidis*, 748–749, 754
  parainfluenza viruses and, 1152–1153
  proinflammatory, stimulated by *Pseudomonas aeruginosa*, 866
  in pyogenic arthritis, 487
  pyrogenic, 93–94
  release of, *C. difficile*, 390
Cytolysis, by *Entamoeba histolytica*, 1312

Cytomegalovirus (CMV), 195*t*, 1073–1081, 1080*b*
  acute bilateral lymphadenopathy lymphadenitis from, 139
  antigen detection for, 1435
  antigenemia, 1441
  antiviral drug resistance of, 1079
  biologic response modifiers and, 653
  burn wound infection from, 530
  chronic fatigue syndrome from, 1038*b*
  chronic hepatitis from, 415
  clinical manifestations of, 1076–1078
    in AIDS, 1076
    in premature newborns, 1077
  congenital infection from, 1445
    characteristic manifestations of, 548*t*
    clinical manifestations of, 1076–1077, 1076*t*
    diagnosis of, 1441
    epidemiology of, 1075
    laboratory diagnosis of, 1078
    pathogenesis of, 1074–1075, 1075*t*
    prevention of, 1080, 1080*b*
    treatment for, 1078
  description of, 1073
  diagnosis/detection of, 1441
    blood samples in, 1435
    culture, 1441
    DNA probes, 1441
    IgG, 1441

  - IgM, 1441
  - in peripheral white blood cells, 1441
  - shell vial method for, 1435, 1441
  - specimens for, 1441
- DNA probes for, 1441
- in drug-induced immunodeficiency, 258
- drug resistance to, 1552*t*
- epidemiology of, 1075
  - age-related prevalence, 1075
  - modes of transmission, 1075
  - occupational infection, 1075
- in group childcare, 30
- in HIV infection, 1077–1078
- in HSCT recipients, 573
- immune globulin, 41
- in immunocompromised patients, 1560
  - laboratory diagnosis for, 1078
  - treatment for, 1078–1079
- inflammatory enteritis from, 392
- intranuclear inclusions of, 1441
- laboratory diagnosis of, 1078
- mononucleosis syndrome from, diagnosis of, 1441
- nosocomial infection from
  - epidemiology of, 1075
  - prevention of, 1080
- optimal tests for, 1437*t*–1440*t*
- pathogenesis of, 1073–1075
  - dissemination in, 1074

    - immune response in, 1074
    - persistence in, 1074
    - tissue tropism in, 1074
  - pericarditis from, 274
  - pneumonia from, 238
    - diagnosis, 259–260
    - in immunocompromised, 257
    - risk factors for, 589
  - pretransplant screening for, 1437*t*–1440*t*
  - prevention of, 1079–1080
    - in healthcare-acquired infection, 1080
    - in maternal and congenital infection, 1080*b*
  - retinitis from, 510*t*, 511–512, 512*f*
  - serologic tests for, 1078, 1078*b*
  - shedding of, 1441
  - in transplant-associated pneumonia, 258
  - in transplant recipients, 569–570
    - chorioretinitis, 569
    - diagnosis of, 569–570
    - disseminated, 569
    - hematopoietic stem cell transplantation, 1077
    - , solid-organ transplantation, 1077
    - treatment for, 1079
  - treatment of infections for, 1078–1079, 1557, 1561
  - vaccine for, 1080
- Cytopathic effects, 1435
  - adenoviruses producing, 1100
  - enteroviruses and, 1212–1213

  of HSV, 1062

Cytopenia, detection of, 617*t*

Cytospinning, in cerebrospinal fluid, 1426

Cytotoxic/cytolytic T lymphocytes (CTL)

  EBV-specific and, 1092

  in HIV-1 infection, 665

  for influenza viruses, 1183

Cytotoxin-associated gene pathogenicity island, of *Helicobacter pylori*, 934–935

D

D-test (disk diffusion), 703

Dacryoadenitis, 519, 519*f*

Dacryocystitis, 519, 519*f*, 1541

Dactylitis

  blistering distal, 441

  in tuberculosis, 798

Dalbavancin, 1516

  dosage for, 1527*t*–1530*t*

  pharmacokinetics of, 1499*t*–1505*t*

  spectrum of activity of, 1506*t*–1511*t*

  treatment for, *Staphylococcus aureus*, 704

Dandruff, *Malassezia* and, 1252

Dapsone

  adverse effects of, 1584

  for *Pneumocystis jirovecii (carinii)* pneumonia, 1268, 1268*t*

  for *Toxoplasma gondii* infection, 1361, 1361*t*

Daptomycin, 732, 1517

  - dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*
  - mechanism of action of, 1471
  - pharmacokinetics of, 1499*t*–1505*t*
  - resistance to, 1471
  - spectrum of activity of, 1506*t*–1511*t*
  - treatment for
    - coagulase-negative staphylococci (CoNS), 710
    - *Leuconostoc* infection, 747
    - *Staphylococcus aureus*, 704
- Darkfield microscopy, 690
- Darunavir (DRV), 682*t*, 1490*t*–1498*t*
- Dasabuvir, copackaged with ombitasvir-paritaprevir-ritonavir, 1558
- de Quervain thyroiditis, 144
- Deafness, viral infections causing, 559
- Deconditioning, fatigue of, Fatigue
- Decongestants, for common colds, 201
- Deerpox virus, 1049*t*
- DEET
  - for *Plasmodium* infection prevention, 1349
  - for prevention, of Rocky Mountain spotted fever *(Rickettsia rickettsii)*, 957
  - for tickborne infections, 546
- *α*-Defensins, 86
- Deferoxamine, as mucormycosis risk factor, 1248
- Definitive therapy
  - for bacterial infections, in neonate, 554
  - for infected neonate, 548–549
- Dehydration

  in orolabial infection, 1057
  Shigella infection causing, 844
  Vibrio cholerae infection causing, 876
    management of, 877, 877*t*
Delayed-type hypersensitivity, rubeola virus infection (measles) and, 1170
Delftia acidovorans (Comamonas acidovorans), 857
Delftia species, 857
Delirium, in recrudescent typhus *(Rickettsia prowazekii)*, 958
Delta sign, 335
Delta virus, 1045*t*
  infections, 1046*t*
Demeclocycline, pharmacokinetics of, 1499*t*–1505*t*
Dendritic cells, 87–88
Dengue fever, 1129
Dengue hemorrhagic fever, 1129
Dengue shock syndrome, 1129
Dengue viruses, 1129
Dental caries, 193
  Rothia dentocariosa role in, 787
Dental infections
  anaerobic cocci causing, 1018
  viridans streptococci causing, 734
Dental procedures, endocarditis pathogenesis and, 262
Dental trauma, endocarditis and, 734
Deoxycholate-citrate agar, 1424*t*
Deoxyribonuclease, recombinant human, 650
Depression

  chronic fatigue syndrome causing, 1040
  in HCV, 1141
  mefloquine, contraindication for, 1347–1349
  Taenia solium neurocysticercosis causing, 1403–1404
Dermacentor andersoni, 1119, 1120*f*
Dermal sinus tract, in recurrent meningitis, 296, 297*f*
Dermatitis
  cercarial, 1420
  disseminated gonococcal infection causing, 762
  hookworm infections causing, 1376
  pruritic, 1392
Dermatologic infections
  in internationally adopted children, 36
  with *Mycoplasma pneumoniae*, 1024*t*
  in sexually transmitted infection syndromes, 351*t*, 352–353
Dermatolymphangioadenitis, acute, 1390
Dermatomyositis, 188
Dermatophytes, 1282–1287
  in genital dermatosis, 356
Dermoid cysts, in recurrent meningitis, 296, 298*f*–299*f*
Desquamation, of staphylococcal exfoliative toxin, 113
Developmental delay, in rubella virus, 1146
Device-associated infections, bloodstream infections and, 593
Device-related infections
  in cancer, 579, 579*t*
  clinical syndromes of, 600–612
  CNS devices, 609–610, 610*b*
  determinants of, 601*b*

- in orthopedic devices, 610–611
- in pacemakers and ventricular assist devices, 608–609
- pathogens of, 601, 601*b*
- in peritoneal catheters, 610
- in prosthetic valves, patches, and vascular grafts, 607–608
  - clinical manifestations and laboratory diagnosis of, 607, 607*b*
  - epidemiology and pathogenesis of, 607, 607*b*
  - management and outcome of, 608
  - prevention of, 608, 608*b*
- in urinary catheters, 611–612

Deworming programs
- for *Ascaris lumbricoides*, 1375
- of pets, for prevention, of *Dipylidium caninum* infection, 1395

Dexamethasone, 742
- for acute bacterial meningitis, 286
- for endophthalmitis, 516*t*
- for meningitis, 930

Diabetes mellitus
- *Coccidioides immitis* (coccidioidomycosis) and, 1277
- enteroviruses causing, 1211
- insulin-dependent, congenital rubella syndrome and, 1145–1146
- as mucormycosis risk factor, 1248

Dialysis, pharmacokinetics of, 1481, 1481*t*

Dialyzable drugs, 1480

Diaper dermatitis, 1232

Diaphragm, splinting, 173

Diaphragmatic irritation
- abdominal pain in pneumonia from, 174

  - acute pain, 173
- Diarrhea
  - acute infectious, 27
    - *Giardia intestinalis* causing, 1318–1319
  - adenoviruses causing, 1099
  - *Aeromonas* infection causing, 854
  - in AIDS/HIV infection, 392, 679
  - antimicrobial-associated, 379
  - *Bacillus cereus* infections causing, 772
  - *Balantioides coli* causing, 1303
  - bloody
    - *Entamoeba histolytica* infection causing, 1313
    - *Salmonella* Typhi causing, 840
    - *Shigella* causing, 843–844
    - *Yersinia enterocolitica* causing, 847
  - *Campylobacter upsaliensis* causing, 904
  - chronic
    - *Cystoisospora* and *Cyclospora* causing, 1321–1322
    - *Giardia intestinalis* causing, 1319
    - microsporidia causing, 1335
  - *Cryptosporidium* causing, 1307
  - *Cyclospora* causing, 1321–1322
  - *Cystoisospora belli* causing, 1321
  - *Diphyllobothrium* infection causing, 1394–1395
  - enteroviruses causing, 1210–1211
  - *Escherichia coli* causing, 27, 816
  - in group childcare, 377
  - healthcare-associated, 379

in hospitals, 379
in HSCT recipients, 575
in immunosuppressed children, 380
inflammatory, 380
    Campylobacter causing, 900
Listeria monocytogenes causing, 783
non-inflammatory, 378*f*
noroviruses causing, 1221
in out-of-home childcare settings, 380
persistent, 380
Plesiomonas shigelloides causing, 832
rubeola virus infection (measles) and, 1173
Salmonella causing, 839
Strongyloides fuelleborni causing, 1380
travelers', 83–85, 380
    Aeromonas infection, 854
    Cryptosporidium causing, 1307
    empiric treatment for, 84
    fluoroquinolones for, 84
    loperamide for, 84
    preventive measures of, 84, 84*b*
    risk factors of, 380
    treatment for, 84–85, 84*t*
Trichinella spiralis causing, 1387
Trichuris trichiura causing, 1378
viral gastroenteritis and, 383
watery, 380
    Aeromonas infection causing, 854

    - astrovirus causing, 1225
    - clinical features (cholera) of, 877*t*
    - *Cryptosporidium* causing, 1307
    - differential diagnosis of, 844
    - *Escherichia coli* causing, 817
    - *Shigella* causing, 843–844
    - *Vibrio cholerae* infection causing, 876, Gastroenteritis
- Diarrheal syndrome, 398
- Diazepam, for *Clostridium tetani* infections, 998
- Dibromopropamidine, for *Acanthamoeba* keratitis, 1341
- Dicloxacillin
  - for dacryoadenitis, 519
  - dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*
- *Dictyostelium discoideum*, 1310–1312
- Didanosine (ddI), 682*t*
  - dosing of, 1490*t*–1498*t*
- *Dientamoeba fragilis*, 1316–1317
- *N,N*-Diethyl-*m*-toluamide (DEET), DEET
- Diethylcarbamazine (DEC), treatment for
  - loiasis, 1393
  - lymphatic filariasis, 1390, 1572
  - *Mansonella streptocerca*, 1393
  - systemic nematodes, 1571
- DiGeorge syndrome
  - due to interstitial deletions, of chromosome 22, 639, 640*t*
  - *Giardia intestinalis* causing, 1319

Digoxin, for myocarditis, 273

Dihydrofolate reductase (DHFR) inhibitors, 1570

Diloxanide furoate, protozoan infection treatment of, 1568

  Entamoeba histolytica, 1568

Dimeticones, for pediculosis treatment, 1296

, Dimorphic fungi

  Blastomyces dermatitidis and, 1270

  Coccidioides, 1276

  Histoplasma capsulatum and, 1259

  isolation of, 1431

Dipetalogaster maximus, 1369, 1370*f*

Diphtheria, tetanus, and pertussis (DTP) vaccines, 59–60, 59*t*

  diphtheria-tetanus (dT) vaccine, 777

  DTaP

    for children, younger than 7 years of age, recommendations for, 48*f*–51*f*, 59–60

    for tetanus prevention, 998*t*

Diphtheria toxoid, acellular pertussis vaccine (Tdap), for trauma-related infection, 523

Diphyllobothrium (diphyllobothriasis), 1394–1395

  clinical manifestations of, 1394–1395

  description of, 1394–1395

  eggs of, 1394

  epidemiology of, 1394

  laboratory findings and diagnosis of, 1395

  larvae of, 1394

  prevention of, 1395

  treatment of, 1395

Diphyllobothrium cordatum, 1394

Diphyllobothrium dalliae, 1394

Diphyllobothrium dendriticum, 1394

Diphyllobothrium lanceolatum, 1394

Diphyllobothrium latum, 1293*t*, 1394

Diphyllobothrium nihonkaiense, 1394

Diphyllobothrium pacificum, 1394

Diphyllobothrium ursi, 1394

Dipylidium caninum, 1293*t*, 1395

Direct fluorescent antibody (DFA) assays

- for *Bordetella pertussis*, 892–893
- for *Chlamydia trachomatis*, 912
- for *Giardia intestinalis*, 1319
- for measles virus, 1443–1444
- for *Mycoplasma pneumoniae*, 1446
- for RSV, 1442

Dirofilaria immitis, 1388*t*, 1393

Dirofilaria repens, 1388*t*, 1394

Dirofilaria tenuis, 1388*t*, 1394

Dirofilariasis, 1393–1394

Disability-adjusted life years, parasitic infection burden and, 1291

Disease control, public health policy and, 7–8

Disease outcome, confounding variable and risk factor, 6*f*

Disinfectants, for noroviruses prevention, 1223

Disinfection, sterilization, and infectious waste, removal of, 17–19

Disk diffusion testing, 1427, 1474–1475, 1475*f*–1476*f*

Diskitis, 189, 189*t*, 493–495

- clinical manifestations of, 494, 494*t*

diagnosis of, 494–495, 495*f*
differential diagnosis of, 494
epidemiology and etiology of, 493, 493*t*–494*t*
management of, 495
outcome of, 495
pathogenesis and pathologic findings of, 494
Staphylococcus aureus causing, 697
vertebral osteomyelitis *versus*, 484, 493
Disseminated disease, microsporidia associated with, 1334
Distant breath sounds, 171
Distribution, of drugs, 1483–1484, 1484*t*
DNA, of Herpesviridae, 1055
DNA-DNA hybridization, bacterial, identification by, 691
DNA probes, for cytomegalovirus (CMV), 1441
DNA sequencing
for resistance detection, 1475, Genome
DNA viruses, 1047*f*
Dobrava virus, 1132–1133, 1133*t*–1134*t*
DOCK8 deficiency, 640*t*, 641
Dog(s)
Echinococcus granulosus in, 1404, 1405*f*
Echinococcus multilocularis in, 1408
Echinococcus vogeli in, 1409
Leishmania reservoir in, 1333
rabies virus in, 1177
Strongyloides stercoralis in, 1379
Taenia serialis in, 1410
tapeworm *(Dipylidium caninum)* of, 1395, 1396*f*

  - *Toxocara* infection transmission in, 1382
- Dolutegravir (DTG), 682*t*
- Donovan bodies, 823
- Donovanosis, *Klebsiella (Calymmatobacterium) granulomatis* (donovanosis)
- Dopamine, for septic shock management, 101
- Doripenem
  - dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*
- Dorsal root ganglia, latent VZV infection in, 1065
- Dosing, of antimicrobial agent, 1464–1465
- Double sickening, 231
- Downey cells, 1091
- Doxycycline, 1519, 1572
  - antibacterial agents with antiprotozoan activity, 1570
  - dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*
  - pharmacokinetics of, 1499*t*–1505*t*
  - prophylaxis, for *Plasmodium*, 1348*t*
  - resistance to, 1474
  - spectrum of activity of, 1506*t*–1511*t*
  - treatment for
    - *Babesia* (babesiosis), 1300–1302
    - *Bacillus anthracis* infections, 771
    - *Borrelia burgdorferi* (Lyme disease), 984, 984*b*
    - *Borrelia* species infection, 986
    - *Brucella* species (brucellosis), 888, 889*t*
    - *Chlamydia trachomatis* infections, 913*t*

    Coxiella burnetii infections, 917–918
    Ehrlichia and *Anaplasma* infection, 921–922
    epididymitis, 371–372
    Leptospira infections, 979–980
    murine typhus *(Rickettsia typhi)*, 960
    Mycoplasma pneumoniae infection, 1027
    Neisseria gonorrhoeae infections, 763–764
    onchocerciasis, 1392, 1572
    P. vivax, 1572
    Plasmodium infections, 1345, 1345*t*–1346*t*, 1348*t*
    R. felis infections, 961
    Rickettsia akari (rickettsialpox), 961
    Rickettsia prowazekii, 959
    Rocky Mountain spotted fever *(Rickettsia rickettsii)*, 955
    severe malaria, 1572
    tickborne infections, 545–546
    urethritis, 359
    Vibrio cholerae infection, 877–878
    Yersinia pestis, 849
Dracunculus medinensis, 1293*t*
DRESS syndrome, eosinophilia from, 1456
Droplet transmission, of healthcare-associated infections, 11
Drug abuse, intravenous
  Bacillus cereus infections causing, 772
  wound botulism and, 1005
Drug-drug interactions, 1482–1485
Drug hypersensitivity reactions, 108–111
Drug-induced aseptic meningitis, 304

Drug-induced hyperplasia related to hypersensitivity, generalized lymphadenopathy from, 134

Drug-induced meningitis, 298

Drug-resistant tuberculosis, 792

Dry eyes, infective keratitis from, 505

"Duck hunter's itch", 1385

Duffy blood group antigen, 1343

Duke schema, for diagnosis of endocarditis, 266, 266*b*

Duodenal aspirate, transport systems and media inoculated routinely in, 1423*t*

Duodenal biopsy, for *Giardia intestinalis*, 1319

Duodenal injury, retroperitoneal abscess after, 435

Dysentery, 380

- acute, 388
- amebic, 391, 1313
- *Trichuris* causing, 1378

Dyspnea, *Aspergillus* species and, 1238–1239

Dysuria

- discharge/dysuria syndrome, 349, 350*t*–351*t*
- epididymitis and, 371
- in urinary tract infections, 344

E

E-cadherin, internalin and, 782

E-test, 1428

Ear

- cartilage, burn wound infections on, 529
- congenital defect, in recurrent meningitis, 296

infections
    cancer and, 589–590
    treatment for, 1544–1546, 1545*t*
Early-onset bacterial septicemia, 547–548
Early-onset infection, in neonate, 550, 550*t*
Eastern Association for the Surgery of Trauma (EAST), 526
Eastern equine encephalitis virus, 311, 322, 1127
  diagnosis/detection of, 1445
  optimal tests for, 1437*t*–1440*t*
Ebola Zaire virus, 1190
Ecchymoses, 453–454
Echinacea, for common colds, 201, 1220
Echinocandins
  in antifungal susceptibility testing, 1432
  for *Aspergillus* infection treatment, 1243
  for *Candida* infections, 1236
  for *Cryptococcus* infections, 1258
  as empiric antifungal therapy, 583–584
  for systemic fungal infections, 1535*t*, 1539–1541
Echinococcosis
  alveolar, *Echinococcus multilocularis*
  cystic, *Echinococcus granulosus*
  hepatic, 1406
  polycystic, 1409
Echinococcus granulosus, 1404–1408
  cervid, 1404
  clinical manifestations of, 1406
  description of, 1404, 1405*f*–1406*f*

  eosinophilic meningitis from, 340*t*
  epidemiology of, 1404–1406
  genetic types, 1404
  hydatid cysts, 1404, 1406*f*
    diagnosis of, 1406, 1407*f*
    in liver, 1406, 1407*f*
    in lung, 1406, 1407*f*
    percutaneous aspiration and, 1407–1408
    rupture, 1406
    total removal of, 1406
  laboratory findings and diagnosis of, 1406, 1407*f*
  life cycle of, 1404, 1405*f*
  prevention of, 1408
  strains of, 1404
  treatment for, 1406–1408
    chemotherapy, 1407
    percutaneous treatments, 1407–1408
    results of, monitoring of, 1408
    surgery, 1406–1407
Echinococcus multilocularis (alveolar echinococcosis), 1408–1409
  clinical manifestations of, 1408
  description of pathogen, 1408–1409
  epidemiology of, 1408
  laboratory findings and diagnosis of, 1408, 1409*f*
  prevention of, 1409
  treatment for, 1408–1409
Echinococcus species, 1404–1410, 1409*b*–1410*b*
  eosinophilia from, 1454–1456

Echinococcus vogeli, 1409
Echinostome infections, 1413
Echinostomiasis, 1412*t*
Echocardiography
  for endocarditis, 265
  M-mode, for pericarditis, 276
  for myocarditis, 272
  for pericarditis, 276
  two-dimensional, for pericarditis, 276
Echovirus(es), 1205
  aseptic meningitis from, 1207
  clinical manifestations of, 1207
  in group childcare, 30
  myositis from, 1210
  neonatal infections from, 1211
  optimal tests for, 1437*t*–1440*t*
  serotypes of, 1205, 1206*t*, Enterovirus(es)
Echovirus 11, hepatitis from, 1211
Ecologic fallacy, 2
Econazole, for superficial infection treatment, 1533
, Economic analysis, of disease prevention, 8
Ecthyma, 437*t*, 442
Ecthyma gangrenosum, 437*t*, 442, 443*f*–444*f*
  Aeromonas causing, 854
  Pseudomonas aeruginosa causing, 868*t*, 869*f*
  Stenotrophomonas maltophilia causing, 874
Ectocervicitis, 365
Ectoparasites (lice and scabies), 1294–1298

Ectopic pregnancy, pelvic inflammatory disease and, 369
Ectopy, cervical, 368*f*
Eculizumab, 651
Eczema coxsackium, 113
Edema
  mucosal, *Trichuris trichiura* causing, 1377–1378
  periorbital, *Trichinella spiralis* infections causing, 1387
Edwardsiella, 830
Edwardsiella tarda, 830
Efavirenz, 682*t*, 1490*t*–1498*t*
Effect modifiers, 6
  control of, 6
  impact, 6
Efflux systems, in *Pseudomonas aeruginosa*, 869
Eflornithine
  adverse effects of, 1584
  for *T. brucei gambiense* infection, 1572
  for *Trypanosoma brucei* infection, 1369*t*, 1568
Ehrlichia, 918–923
  chronic fatigue syndrome from, 1038*b*
  clinical manifestations of, 919*t*, 920–921
  considerations in, 922
  description of, 918–919, 920*f*
  diagnostic tests for, 921, 922*b*–923*b*, 922*f*
  differential diagnosis of, 921
  epidemiology of, 919–920
  generalized lymphadenopathy from, 131
  laboratory findings of, 921

  microbiology of, 922
  morulae and, 918
  opportunistic infections in, 921
  prevention of, 922
  thrombocytopenia from, 1458
  treatment for, 921–922
Ehrlichia chaffeensis, 918, 919*t*
  cross-reactivity in, 543–545
  human monocytic ehrlichiosis from, 543*t*
  laboratory testing of, 318*t*–321*t*
Ehrlichia ewingii, 918, 919*t*
  agents, vectors, and geographic distribution of, 543*t*
  clinical and laboratory manifestations of, 544*t*–545*t*
  laboratory testing of, 318*t*–321*t*
Ehrlichia phagocytophilum, *Anaplasma phagocytophilum*
Eikenella, 859–863
  clinical manifestations of, 860–862, 860*f*–861*f*
  microbiology of, 859–860
  pathophysiology and epidemiology of, 860
  treatment and prevention of, 862
Eikenella corrodens, 859, 862*b*–863*b*
  brain abscesses from, 735*f*
  clinical manifestations of, 860, 861*f*
  human bite infection from, 532
  infections from, 860
  paronychia from, 441
  skin infection after trauma, 523
  treatment and prevention of, 862

Ekiri syndrome, 844
Elastase, neutrophil, in cyclic neutropenia, 125–126
Electrocardiograph (ECG), for *Trichinella spiralis* infections, 1387
Electroencephalography (EEG)
  for altered mental status, 181
  for encephalitis, 317
  for HSV encephalitis, 1059
Electrolytes
  composition of rehydration solutions, 876*t*
  diarrheal stools, cholera and, 876*t*
  imbalance
    Plasmodium infections causing, 1344–1345
    Vibrio cholerae infection and, 876
Electromyography
  for *Clostridium botulinum*, 1003
  for Guillain-Barré syndrome, 326
Elek test, for diphtheria toxin, 773
Elementary body (EB)
  Chlamydia trachomatis and, 908
  Chlamydophila (Chlamydia) pneumoniae and, 906
Elimination, of antimicrobial agents, 1484
Elizabethkingia meningoseptica, 856
Elvitegravir (EVG), 682*t*
Emboli
  brain abscess and, 331
  in endocarditis
    complication, 269
    pathogenesis, 263

Embryopathy, varicella in pregnancy, 1068
Empedobacter brevis (Flavobacterium breve), 856
Empedobacter species, 857–858
Empiric antifungal therapy, 583–584
Empiric therapeutic regimens, 582–583
Empyema, 244–247, 739–740
  complicated, 245
  pleural, 248*f*
Empyema necessitans, 245–246
Emtricitabine, 682*t*
  dosing of, 1490*t*–1498*t*
Enanthems, enterovirus infections causing, 1207–1208, 1208*f*–1209*f*
Encephalitis, 305–322
  Acanthamoeba causing, 1339
  in acquired rubella, 1147
  acute, rubeola virus infection (measles) and, 1173
  adenovirus causing, 318*t*–321*t*
  Anaplasma phagocytophila causing, 318*t*–321*t*
  anti-NMDAR, 312, 322
  arboviruses causing, 311
  bacterial causes of, 180, 312
  Bartonella henselae causing, 312
  Borrelia burgdorferi causing, 312
  Brucella causing, 318*t*–321*t*
  clinical approach of, 317–321
  clinical manifestations of, 313–316, 313*t*–314*t*
  complications and prognosis of, 322
  conditions mimicking, 310*b*

in congenital rubella, 1146
cytomegalovirus (CMV) causing, 318*t*–321*t*
diagnostic criteria for, 315*b*
differential diagnosis of, 313–316, 317*t*
Eastern equine encephalitis (EEE), 311, 322
enterovirus causing, 310, 318*t*–321*t*, 1208*t*, 1209
    brainstem encephalitis and, 1210
epidemiology of, 305–312, 306*t*–310*t*
Epstein-Barr virus (EBV) causing, 311, 322
etiologic agents of, 305–312, 306*t*–310*t*
free-living amebas causing, 312
fungi causing, 312
herpes simplex virus 1 (HSV-1) causing, 318*t*–321*t*, 322
herpes simplex virus 2 (HSV-2) causing, 318*t*–321*t*
herpesviruses causing, 311
histology of, 313
human herpesvirus 6 causing, 318*t*–321*t*, 1084
human immunodeficiency virus (HIV) causing, 318*t*–321*t*
human metapneumovirus causing, 318*t*–321*t*
human parechoviruses causing, 310–311
immunocompromised hosts in, 317
infant botulism *versus*, 1003*t*
influenza A/B virus causing, 318*t*–321*t*
initial diagnostic evaluation for, 321*b*
Japanese encephalitis virus causing, 311
JC polyomavirus causing, 318*t*–321*t*
L. monocytogenes causing, 322
La Crosse virus (LACV) causing, 311

laboratory findings of, 313*t*–314*t*, 321
Leptospira causing, 318*t*–321*t*
lymphocytic choriomeningitis virus (LCM) causing, 318*t*–321*t*
management of, 321–322
measles virus causing, 318*t*–321*t*
microsporidia associated with, 1334
mumps virus causing, 318*t*–321*t*, 1159
Mycobacterium tuberculosis causing, 322
Mycoplasma pneumoniae causing, 312, 318*t*–321*t*, 1024
in neonates, 316–317
parasites causing, 312
parvovirus B19 causing, 318*t*–321*t*
pathogenesis of, 312–313
Plasmodium falciparum causing, 312
Powassan virus causing, 311
prevention of, 322
rabies virus causing, 311
respiratory syncytial virus causing, 318*t*–321*t*
Rickettsia causing, 318*t*–321*t*
Rift Valley fever and, 1134
Rocky Mountain spotted fever (RMSF) and, 312
rotavirus causing, 318*t*–321*t*
rubella virus causing, 318*t*–321*t*
special hosts in, 316–317
St. Louis encephalitis virus causing, 311
Toxoplasma gondii causing, 312
treatment of, 322
Treponema pallidum causing, 318*t*–321*t*

- varicella-zoster virus (VZV) causing, 311
- viruses causing, 310–312
- West Nile virus causing, 311, 322, 1130

Encephalitozoon, 1335*t*

Encephalitozoon cuniculi, 1334, 1335*t*

Encephalitozoon hellem, 1335*t*

Encephalitozoon intestinalis, 1335*t*

Encephalocele, recurrent meningitis and, 297

Encephalopathy
- acute necrotizing, 315*b*, 316*f*
- cat-scratch disease causing, 180, 885
- in HSCT recipients, 576, 576*b*
- influenza and, 1184
- metabolic, *Plasmodium* infections causing, 1343–1344
- progressive HIV, 670

Endemic syphilis (bejel), 977

Endocardial thrombosis, *Trypanosoma cruzi* infections causing, 1371

Endocarditis, infective, 261–270
- *Abiotrophia* causing, 734
- *Aggregatibacter actinomycetemcomitans* causing, 967
- aortic valve, *Kurthia bessonii* causing, 789
- *Bacillus cereus* causing, 772
- bacteremia associated, 262, 263*t*, 264
- blood cultures for, 264
  - negative, 262
- brain abscess and, 331, 338
- *Brucella* species (brucellosis) causing, 888, 889*t*
- in burn patients, 529

Cardiobacterium hominis causing, 968
Cellulosimicrobium (Oerskovia) and, 789
clinical manifestations of, 263–264, 264*t*
    symptoms, 263–264, 264*t*
coagulase-negative staphylococci (CoNS) causing, 261–262, 709
complications of, 264, 269
congenital heart disease and, 262, 262*t*
culture-negative, 262, 734
dental trauma and, 734
diagnostic criteria for, 266, 266*b*
    Duke schema, 266*b*
differential diagnosis of, 264
enterococci causing, treatment of, 267*t*, 268
epidemiology of, 262, 262*t*
Erysipelothrix rhusiopathiae causing, 786
etiologic agents and associated risk factors of, 261–262, 262*t*
gonococcal, 762
Granulicatella causing, 734
imaging for, diagnostic, 265–266, 265*f*–266*f*
Kingella kingae causing, 261–262, 947
    treatment for, 948
laboratory findings and diagnosis of, 264–266
    ancillary tests, 264, 264*t*
    diagnostic imaging, 265–266, 265*f*–266*f*
    microbiologic evaluation, 264–265, 265*t*
Lactobacillus causing, 788
left-sided, 264, 269
Listeria monocytogenes causing, 784

management of, 266–269
  anticoagulation, 269
  definitive antibiotic therapy, 267–269, 267*t*–268*t*
  doses of antimicrobials, 268*t*
  duration of therapy, 267–269
  empiric antibiotic therapy, 266–267, 267*t*–268*t*
  outpatient, 269
  surgery, 269, 269*t*
mortality rate of, 261, 270
, neonatal, 262
pathogenesis and pathologic findings of, 262–263
  native valve, 262–263, 263*t*
  pacemaker and ventricular assist device infections, 263
  pathologic lesions, 263, 263*f*
  postoperative, 263
pathologic lesions in, 263, 263*f*
physical examination of, 264
postoperative, 263
posttreatment management of, 270
prevention of, 72*t*–74*t*, 78, 78*b*, 270
prognosis of, 269–270
Pseudomonas aeruginosa causing, 868*t*
right-sided, 262–263
risk factors of, 261–262
Rothia dentocariosa causing, 787
Staphylococcus aureus causing, 698–700
Streptococcus pneumoniae causing, 261–262
viridans streptococci causing, 734

    - therapeutic recommendations for, 735
- Endocarditis-like intravascular infections, 270
- Endocervicitis, 365–366
- Endogenous pyrogens, 93
- *Endolimax nana*, 1309–1310, 1309*f*–1310*f*, 1572
- Endomyocardial biopsy, 272–273
- Endophthalmitis, 514–517
  - *Bacillus cereus* infections causing, 772
  - bleb-related, 514
  - clinical manifestations of, 515, 515*f*
  - coagulase-negative staphylococci (CoNS) causing, 710
  - diagnostic evaluation for, 515, 515*f*
  - endogenous, 514
  - epidemiology and host factors of, 514
  - etiologic agents of, 514
  - exogenous, 514
  - management of, 515–516, 516*t*, 1544, 1544*t*
  - outcome of, 516
  - pathophysiology of, 514–515
  - postoperative, 514
  - prevention of, 516
  - *Staphylococcus aureus* and, 696
- Endospores, of *Coccidioides immitis* (coccidioidomycosis), 1276, 1276*f*
- Endothelial cells
  - in meningitis pathology, 280
  - *Treponema pallidum* (syphilis) and, 969
- Endotoxin (lipopolysaccharide), 690
  - as exogenous pyrogens, 93

- in *Neisseria meningitidis*, 748–749

Endotracheal intubation
- for infant botulism, 1004
- for meningococcal disease, 754

Enfuvirtide, 682*t*, 683

Entamoeba, 1310–1312, 1316–1317

Entamoeba bangladeshi, 1316

Entamoeba chattoni, 1316

Entamoeba coli, 1309*f*, 1316, 1572

Entamoeba dispar, 1310–1312, 1316
- epidemiology of, 1312
- infection, 1572

Entamoeba gingivalis, 1316

Entamoeba hartmanni, 1309*f*, 1316, 1572

Entamoeba histolytica (amebiasis), 1310–1316
- brain abscess from, 329
- clinical manifestations of, 1312–1314
  - acute fulminant or necrotizing colitis, 1313
  - amebic colitis (intestinal amebiasis), 1313, 1313*f*, 1313*t*
  - ameboma, 1313
  - growth and cognitive complications, 1314
  - liver abscess, 1313–1314, 1314*t*
  - noninvasive intestinal infection, 1312–1313
- description of, 1310–1312, 1311*f*
- detection of, 1432–1433
- diloxanide furoate for, 1568
- dissemination of, 389–390
- enteric illnesses from, 399*t*–405*t*

- epidemiology of, 1312
- etiologic agents, of non-STI infectious GUD, 353
- immunity of, 1312
- inflammatory enteritis from, 389–390, 389*t*
- key points in, 1315*b*
- laboratory findings and diagnosis of, 1314
- mesenteric lymphadenitis from, 157
- pathogenesis of, 1312
- prevention of, 1315
- treatment for, 1314–1315, 1315*b*
- trophozoites of, 389–390
- in water supplies, 390

Entamoeba invadens, 1316

Entamoeba moshkovskii, 1310–1312, 1316

Entamoeba polecki, 1309*f*, 1316, 1572

Entecavir, 1558–1559
- dosing of, for impaired renal function, 1490*t*–1498*t*

Enteric bacterial infections, 27–28

Enteric diseases, transmitted through food, water, and zoonotic exposures, 397–409
- clinical syndromes of, 406
- complications of, 408
- diagnosis of, 407
- epidemiology of, 398–406
- management of, 407–408
- pathogenesis of, 406
- prevention of, 408–409
- surveillance and outbreak detection of, 406–407

Enteric infections
- acute abdominal pain from, 175–176
- generalized lymphadenopathy from, 131
- in group childcare, 25–28, 26*t*
- in HSCT recipients, 575
- in refugee and internationally adopted children, 35, 35*t*

Enteric viral infections, 27

Enteritis
- eosinophilic, *Ancylostoma caninum* causing, 1376–1377
- HIV infection causing, 679
- inflammatory, 388–393
  - acute, 388*t*
  - causes of, 389, 389*t*
  - chronic, 388, 388*t*
  - classification of, 388–389
  - complications of, 389*t*
  - diagnostic evaluation of, 390–392, 391*t*
  - differential diagnoses of, 388*t*
  - epidemiology of, 390, 390*t*
  - etiologic agents of, 389–390
  - in immunocompromised host, 392, 392*b*
  - infants with, 393
  - management of, 392–393, 393*t*
  - noninfectious causes of, 388–389
  - pathogenesis of, 389*t*, 390
  - risk factors of, 390, 390*t*
  - tests to confirm cause of, 391–392
- in sexually transmitted infection syndromes, 350

Enterobacter, 824–827
  AmpC-type β-lactamase for, 826
  appendicitis from, 429
  clinical manifestations of, 825
  diagnosis and management of, 826*b*
  epidemiology of, 824–825
  extended-spectrum β-lactam/β- lactamase inhibitor combination drugs for, 826
  folliculitis from, 440
  fracture-associated infection from, 526
  meningitis from, 825
  microbiology of, 824–825
  nosocomial infections from, 825
  plasmids of, 826
  species of, 824
  stably de-repressed mutants in, 826
  treatment for, 825–826
  urinary tract infections from, 343
Enterobacter aerogenes, 824
Enterobacter agglomerans, 824
Enterobacter cloacae, 824
Enterobacteriaceae
  antimicrobial susceptibility testing for, 1427, 1428*t*
  Gram-negative bacteria, 343
  hospital-associated infection from, 565
  isolation of, media used for, 1425*t*
  less commonly encountered, 829–831, 831*b*
Enterobius vermicularis, 1373, 1378–1379

- acute abdominal pain from, 175
- appendix infection from, 1379, 1379*f*
- clinical manifestations of, 1374*b*, 1379, 1379*f*
- eggs of, 1374*f*, 1378
- eosinophilia from, 1454–1456
- epidemiology of, 1378
- infection route of, 1373–1374, 1378
- laboratory findings and diagnosis of, 1374*f*, 1379
- life cycle of, 1378
- prevention of, 1379
- treatment of, 1379

Enterococcal agar, selective, 1424*t*

Enterococcus, 713*t*, 729–732
- antimicrobial resistance of, 731–732, 731*b*, 1469
  - aminoglycoside, 1475
  - intrinsic and acquired, 731
  - linezolid, 1473
- antimicrobial susceptibility testing for, 1428*t*, 1430
- bacterial infections from, in neonate, 549
- biochemical differentiation of, 747*t*
- bloodstream infections from, 730
- clinical manifestations of, 730
- colonization by, 730
- endocarditis from, 732
  - treatment of, 267*t*, 268
- epidemiology of, 730
- Esp virulence factor of, 730
- growth characteristics of, 730*t*

  infection after abdominal trauma, 525
  infections in older children, 730
  intra-abdominal abscess from, 730
  meningitis from, 286, 730
  neonatal infections, 730
  prevention of, 732
  risk factors for, 730
  strategies for, 732
  treatment for, 731–732
  urinary tract infections from, 345, 730
  vanA and *vanB* genes of, 731
  virulence factors of, 730
Enterococcus faecalis, 713*t*, 730
  antibiotic resistance of, 1469
  biochemical/growth characteristics of, 729*t*–730*t*
  catheter-associated BSI and, 732
  clinical manifestations of, 730
  cytolysin and, 730
  endocarditis from, 730
  neonatal infections, 730
  septicemia from, 730
  treatment for, 731
Enterococcus faecium, 713*t*
  antibiotic resistance of, 1471
  antimicrobial susceptibility of, 731*t*
  biochemical/growth characteristics of, 730*t*
  clinical significance of, 729*t*
Enterocytozoon bieneusi, 1335*t*

Enteropathogens, 376
Enterotest capsule, 1433
Enterovirus(es), 1205–1213
  acute bilateral lymphadenopathy lymphadenitis from, 139
  acute pancreatitis from, 419
  antibodies to, 1206, 1443
  aseptic meningitis from, 301–302, 1207
  bronchiolitis from, 234
  cell culture of, 1212–1213, 1443
  chest pain from, 1210
  chronic fatigue syndrome from, 1038*b*
  clinical manifestations of, 1207–1211, 1208*t*
  CNS infections from, 1208–1210
  congenital infections, characteristic manifestations of, 548*t*
  cytopathic effects of, 1212–1213
  diabetes mellitus from, 1211
  diagnosis/detection of, 1443
    RT-PCR, 1443
    specimens for, 1443
  encephalitis from, 310, 1208*t*, 1209
    brainstem encephalitis and, 1210
  epidemiology of, 1206–1207, 1207*t*
  exanthems/enanthems from, 1207–1208, 1208*f*–1209*f*
  fever and prodrome from, 1208
  hand-foot-mouth disease from, 1207
  immunity to, 1206
  immunodeficiency and, 1212
  incubation period of, 1207

isolation methods for, 1212–1213
, laboratory diagnosis of, 1212–1213
meningitis from, 1208–1209
    in X-linked agammaglobulinemia, 621
myocarditis from, 271, 1211
myopericarditis and, 1210
neonatal infections from, 1211–1212
nosocomial postnatal infections from, 1211
ophthalmic infections from, 1210
optimal tests for, 1437*t*–1440*t*
papules and, 445, 445*f*
pathogenesis of, 1205–1206
pericarditis from, 274
picornaviridae and, 1200
in pregnancy, 1211
prevention of, 1213
replication site of, 1205
respiratory infections from, 1208
by RNA, classification of, 1206*t*
serologic examination for, 1213
serotype of, 301
shedding, 1206–1207
spectrum of illness, 1208*t*
traditional biologic classification of, 1206*t*
transmission of, 1207
treatment of, 1213
viremia from, 1206
wild, shedding of, 1443, Coxsackievirus A, Coxsackievirus B,

Echovirus(es)

Enterovirus 70, conjunctivitis causing, 502–503

Enterovirus A6, with vesicles, 448–449

Enterovirus D70, acute hemorrhagic conjunctivitis from, 1209*f*, 1210

Environmental measures, 16–17

Environmental sources, of *Legionella* infections, 948–949

Enzyme immunoassay (EIA)

- for arboviruses, 1445
- for *Blastomyces dermatitidis*, 1273
- for *Bordetella pertussis*, 895
- for *Borrelia burgdorferi*, 983
- for *Chlamydia pneumoniae*, 1446
- for *Chlamydia trachomatis*, 912, 1445
- for *Clostridium difficile*, 1007
- for Colorado tick fever, 1121
- for *Cryptosporidium*, 1307
- for *Echinococcus granulosus* cysts, 1406
- for *Entamoeba histolytica* infection, 1314
- for Epstein-Barr virus (EBV), 1441–1442
- for flavivirus infections, 1131
- for *Giardia intestinalis*, 1319
- for HCV infection, 1139, 1443
- for *Helicobacter pylori* infection, 938
- for *Histoplasma capsulatum*, 1263
- for HIV, 668, 1444
- for HSV, 1441
- for *Legionella pneumophila*, 950–951
- for MMR, 1444

for *Mycoplasma pneumoniae*, 1025, 1446
for *Rickettsia prowazekii*, 959
for *Rickettsia rickettsii*, 955
for RSV, 1442
for *Taenia*, 1397*b*, 1399
for *Treponema pallidum* (syphilis), 972
for *Trypanosoma cruzi*, 1372
for viral infection diagnosis, 1434, 1436
for VZV, 1069, 1441
Enzyme-immunotransfer blot (EITB), for *Taenia solium* neurocysticercosis, 1401
Enzyme-linked virus-inducible system (ELVIS), 1435
Eosin-methylene blue agar, 1424*t*
Eosinophil(s), 629, 1454–1456
recruitment, *Ascaris lumbricoides* infections and, 1375
Eosinophilia, 1454–1456
causes of, 1455*t*–1456*t*
cerebrospinal fluid (CSF), 341
in chronic meningitis, 292–293
clonorchiasis and opisthorchiasis causing, 1414–1415
Diphyllobothrium infection causing, 1395
fascioliasis causing, 1415
Fasciolopsis buski (fasciolopsiasis) and, 1412
Heterophyes and *Metagonimus* infections and, 1413
hookworm infections causing, 1377
paragonimiasis causing, 1416
in refugee and internationally adopted children, 36
Toxocara infections causing, 1381–1382

Eosinophilic meningitis, 339–343
  Angiostrongylus cantonensis causing, 339, 341
  Ascaris lumbricoides causing, 340*t*
  Baylisascaris procyonis causing, 339, 341, 1383
  definition of, 341
  diagnosis and treatment of, 342
  Gnathostoma spinigerum causing, 340*t*, 341–342, 1384
  infectious causes of, 341–342
    bacteria and viruses, 340*t*
    fungi, 340*t*
    helminths, 341–342
    parasites, 340*t*, 342
  noninfectious causes of, 340*t*, 342
  Toxocara canis causing, 340*t*, 342
  Trichinella spiralis causing, 340*t*
Epi-Info, sample size calculation, 6
Epidemic curve, 7, 7*f*–8*f*
Epidemic keratoconjunctivitis, adenoviruses causing, 1098*t*, 1099
Epidemic pleurodynia, 1210
Epidemic typhus, *Rickettsia prowazekii*
Epidemiologic studies
  hypotheses testing in, 2
  understanding of, 9
Epidemiology
  analytic, Analytic epidemiology
  causal inference and impact of bias, 4–5
  definitions and formulas of, 1, 2*t*
  describing illness by person, place, and time, 2

descriptive, 1–2
    case definition, 1
    illness by person, place, and time, 2
    incidence and prevalence, 1–2
    sensitivity, specificity, and predictive value, 1, 2*t*
    surveillance, 1
  of group childcare, 25–31, 26*t*
  principles of, 1–9
Epidermodysplasia verruciformis, HPV causing, 1103
Epidermoid cysts, in recurrent meningitis, 296
Epidermophyton, 1282
Epidermophyton floccosum
  genital dermatosis from, 356
  tinea cruris from, 1285
  tinea pedis from, 1284
  tinea unguium from, 1286
Epididymitis, 371–372, 371*t*
  Brucella species (brucellosis) causing, 888
  clinical manifestations and differential diagnosis of, 371, 373*t*
  epidemiology of, 371
  etiology of, 371
  laboratory findings and diagnosis of, 371, 373*t*
  management and complications of, 371–372
  pathogenesis of, 371
  in pelvic or scrotal pain syndrome, 352
  sexually transmitted, 371
  urethritis and, 360
Epididymo-orchitis, 372

Epidural abscess, 189*t*, 190

  cranial

    clinical manifestations of, 332, 333*t*

    differential diagnosis of, 333

    epidemiology of, 330

Erythroid precursor cells, parvovirus B19 in, 1115

Erythromycin, 1518

- dosage for, 1490*t*–1498*t*, 1527*t*–1531*t*
- pharmacokinetics of, 1499*t*–1505*t*
- resistance to, *Corynebacterium diphtheriae*, 776
- spectrum of activity of, 1506*t*–1511*t*
- treatment for
  - acute conjunctivitis, 503
  - *Bartonella bacilliformis*, 968
  - *Bordetella pertussis*, 896, 897*t*
  - *Campylobacter jejuni* infections, 904
  - *Chlamydia trachomatis* infections, 913*t*
  - eye infections, 1542*t*–1543*t*
  - *Haemophilus ducreyi* (chancroid), 933
  - impetigo, 438
  - *Legionella* infections, 951
  - *Mycoplasma pneumoniae* infection, 1026–1027
  - *Ureaplasma urealyticum*, 1032

Erythromycin estolate, for chlamydial conjunctivitis, 498

Erythromycin ethylsuccinate, for chlamydial conjunctivitis, 498

Erythromycin ribosomal methylase *(ERM)* gene, 703

Escherichia coli, 815–818, 834, 1009

  aggregative adherence fimbriae of, 816

  antibiotic resistance to, 345–346

  appendicitis from, 429

  bacterial infections from, in neonate, 549

  bundle-forming pilus of, 816

  colonization factor antigen (CFA) of, 816

  enteric infections from, 816

  enteroaggregative (EAEC), 389, 815–816

  enterohemorrhagic (EHEC), 389, 389*t*, 815–816

    pathogenesis of, 816, *Escherichia coli* O157:H7

  enteroinvasive (EIEC), 389, 816, 842

    pathogenesis of, 816

  enteropathogenic (EPEC), 389, 816

    attaching and effacing lesion of, 816, 816*f*

  enterotoxigenic (ETEC), 389, 816

  folliculitis from, 440

  in group childcare, 27

  heat-labile enterotoxin (LT) and heat-stable enterotoxin (ST) of, 816

  hemolytic uremic syndrome from, 815–816

  HIV infection causing, 679

  infections

    acute gastroenteritis, 817

    clinical manifestations of, 817

    epidemiology of, 816–817

    extraintestinal and disseminated, 816

  - inflammatory bowel disease, 817–818
  - laboratory findings and diagnosis of, 818
  - pathogenesis of, 816
  - postdiarrheal manifestations of, 817–818
  - prevention of, 818
  - treatment of, 818
  - in urinary tract, 817
  - vaccination for, 818
- infections in hematopoietic stem cell transplant recipients, 574
- in inflammatory enteritis, 389, 389*t*
- meningitis from, 285–286
- mesenteric lymphadenitis from, 157
- necrotizing soft tissue infections from, 470
- neonatal meningitis and, 816
- orchitis from, 372
- P-fimbriae, 343
- P-pili, 343
- pathotypes of, 816
- peritonitis from, 423–424
- pneumonia from, 238
- prostatitis from, 372
- recurrent meningitis from, 295
- scalp abscess from, 470
- screening tests for, 820
- sepsis from, 98
- Shiga-like toxin (STx) of, 816
- Shiga toxin producing, 398, 399*t*–405*t*
- traveler's diarrhea from, 380

  urinary tract infections from, 343, 816
  uropathogenic, 816
  vertebral osteomyelitis from, 484
  virulence of, 343
  virulence traits of, 377
Escherichia coli O157:H7, 818
  in animals, in public settings, 539
  Citrobacter braakii cross-reaction with, 827
  isolation of, media used for, 1425*t*
Esculin, 729–730
Esophagitis, 1232
  cancer and, 590
  HIV infection causing, 679
Etest, 1475, 1475*f*
Ethambutol
  dosing of, 1490*t*–1498*t*
  for tuberculosis, 802–803, 802*t*
Ethionamide
  for childhood TB, 802*t*
  dosing of, 1490*t*–1498*t*
Ethnicity, as risk factors, in urinary tract infections, 344
Ethylenediaminetetraacetic acid (EDTA), 1435
Etravirine (ETR), 682*t*, 683
  dosing of, for impaired renal function, 1490*t*–1498*t*
Eubacterium, 1022
Eucalyptus, oil of, for tickborne infections, 546
Eumycotic mycetoma
  agents causing, 1287–1291, 1288*b*, 1291*b*

  anatomic alterations attributable to, 1289*t*
  antibodies to, 1288
  clinical manifestations of, 1289, 1289*t*
  epidemiology of, 1288–1289
  laboratory findings and diagnosis of, 1289
  microbiology of, 1287
  pathogenesis of, 1288, 1288*f*
  prevention of, 1290
  treatment for, 1289–1290
  virulence and immunity of, 1287–1288
Eustachian tube
  anatomy of, 225–226, 226*f*
  dysfunction, as acute otitis media complication, 226
Ewingella americana, 830
Exanthem(s), 445, 445*b*
  in encephalitis, 313*t*–314*t*
  enterovirus infections causing, 1207–1208, 1208*f*–1209*f*
  varicella lesions and, 1066
Exanthem subitum, 1081–1088
Exanthematous syndromes, generalized lymphadenopathy from, 133
Exchange transfusion, for *Plasmodium* infections, 1345–1346
Exhaled breath hydrogen, for necrotizing enterocolitis, 395
Exogenous pyrogens, 93
Exogenous retroviruses, 1196
Exophiala, 1245–1247
Exophiala werneckii, 1286–1287
Exoserohilum, 1245–1247

Exotoxin A, *Pseudomonas aeruginosa* and, 867*t*

Expectorants, for common colds, 201

Experimental studies, 2

Exposure and outcome variables, 9

Extended-spectrum β-lactamase(s) (ESBLs), 1468*t*, 1470

- in antimicrobial susceptibility testing, 1430
- detection of, 1475–1476, 1476*f*
- for E*nterobacter*, 826
- HAIs (healthcare-associated infections) from, 820
- *Pseudomonas aeruginosa* and, 869
- for *Serratia marcescens*, 836

Extended-spectrum penicillins, 1515

- pharmacokinetics of, 1499*t*–1505*t*
- spectrum of activity of, 1506*t*–1511*t*

External validity, 4

Extracellular infections, antimicrobial therapy for, 1464

Extracorporeal membrane oxygenation, pharmacokinetics of, 1480–1481

Extraintestinal infections, *Plesiomonas shigelloides* causing, 832

- treatment for, 833

Exudate, 244

Eyach virus, 1121

Eye

- anatomy of, 517, 517*f*
- chronic meningitis in, 292
- dry, infective keratitis from, 505
- infections, treatment for, 1541–1544, 1542*t*–1543*t*, 1555*t*
- , paranasal sinuses and, 517, 518*f*

  - red
    - of allergic disorders, 112
    - from endophthalmitis, 515
  - swollen, 517, 517*f*
- Eye drops, treatment for, eye infections, 1543*t*
- Eyelids
  - cellulitis of, 519–520
  - human herpesvirus 6 and, 1083
  - swelling of
    - bacteremic periorbital cellulitis, 520
    - on upper outer aspect, 519

F

- Facial cellulitis, in children, 443
- Facial nerve palsy, 323–324
  - *Borrelia burgdorferi* (Lyme disease) causing, 983
  - etiology of, 323–324, 324*t*
  - incidence of, 323–324
  - pathologic mechanism of, 324
  - treatment of, 324
- Facial pain, unilateral, epidural abscess and, 332
- Facial palsy/paralysis, 222
  - as acute mastoiditis complication, 228
- Facilitywide/systemwide surveillance, 13–14, 14*b*
- Factor G, (1,3)-β-D-glucan, 1242
- Factor H, deficiency of, 627–628
- Factor V, for *Haemophilus influenzae* growth, 926
- Factor X, for *Haemophilus influenzae* growth, 926

Fallot, tetralogy of, brain abscess and, 331
Famciclovir, 1559
  dosage of, 1560*t*
  indications of, 1560*t*
  resistance to, 1552*t*
  for VZV infections, 1070
Familial cold autoinflammatory syndrome (FCAS), 127
Familial cold urticarial (FCU) syndrome, 127
Familial hemophagocytic lymphohistiocytosis (FHL), Hemophagocytic lymphohistiocytosis (HLH)
Familial Mediterranean fever (FMF), 126
  cardinal clinical features of, 126
  course, treatment, and outcome of, 126
  epidemiology and etiology of, 126
Family history, of recurrent infections, 615
Fascia
  diseases, limb pain from, 188
  superficial and deep, 466
Fascial spaces, of head and neck, 136–138, 137*f*, 137*t*
Fasciola gigantica, 1415
Fasciola hepatica, 1293*t*, 1415
  cholecystitis and cholangitis, 421
  eosinophilic meningitis from, 340*t*
Fascioliasis, 1415–1416, 1417*b*–1418*b*
Fasciolopsis buski (fasciolopsiasis), 1293*t*, 1412, 1412*t*
Fastidious bacteria, antimicrobial susceptibility testing for, 1431
Fastidious pathogens, endocarditis from, 262
Fatigue

- clues to alternative causes of, 1042*b*
- of deconditioning, 121–122, 122*b*
  - management of, 122, 122*b*
- HCV infection and, 1138
- persistent, in children, 1043*b*
- postinfectious, syndrome (PIFS), 1039, Chronic fatigue syndrome (CFS)

Favus (tinea favosa), 1285

Febrile agglutinin tests, 1433

Febrile illnesses, nonspecific acute, enterovirus infections causing, 1207

Feces
- examination of, 1432–1433
- transport systems and media inoculated routinely in, 1423*t*

Ferrets, rabies in, 539–540

Ferriprotoporphyrin IX, in *Plasmodium*, 1343

Ferritin, 1451

Fetal infections
- adenoviruses causing, 1100
- *Pasteurella multocida* causing, 861
- *Toxoplasma gondii* causing, 1356, 1359

Fetor oris, in gingivitis, 194

Fetus
- in congenital rubella, 1143
- hemophagocytic lymphohistiocytosis in, 105
- infection and, parvovirus B19 and, 1118
- loss of, parvovirus B19 causing, 1118
- viral infections in, 555–560

    - clinical manifestations of, 558–559
        - cardiac insufficiency, 558–559
        - central nervous system infection, 558
        - deafness, 559
        - ocular abnormalities, 559
        - prematurity and low birth weight, 558
        - pulmonary disease, 559
        - sepsis syndrome, 558
        - spontaneous abortion and stillbirth, 558
        - syndrome of congenital infection, 558, 558*t*
    - epidemiology of, 556–558
    - pathogenesis of, 556

Fever, 93–94, 581–582, 582*b*
- in acute bacterial meningitis, 286, 286*b*
- in acute bacterial sinusitis, 231
- antipyretic therapy for, 94
- in aseptic meningitis, 303
- *Aspergillus* species causing, 1238–1239
- bacteremic periorbital cellulitis and, 520
- brain abscess and, 332
- *Brucella* species (brucellosis) causing, 887
- *Campylobacter fetus* causing, 903
- clinical aspects of, 94
- *Coccidioides immitis* (coccidioidomycosis) causing, 1277
- cooling blanket for, 94
- *Cystoisospora belli* causing, 1321–1322
- EBV infection and, 1089
- *Entamoeba histolytica* infection causing, 1313, 1313*t*

enteric, *Salmonella* causing, 840
enterovirus infections causing, 1207
epidural abscess and, 332
gastrointestinal tract infections and, 376
granulocytopenia and, 578–586
HIV infection causing, 676–677, 677*b*
human herpesvirus 6 causing, 1083
hyperthermia and, 94
induction of, 96*t*
in infants, 94
intra-abdominal abscesses causing, 433
low-grade or falsely perceived, 121
Neisseria meningitidis causing, 752
neutropenia and, 578
pathogenesis of, 93–94, 94*f*
patterns of, 117, 118*b*
periodic, 122–123, 124*t*
peritonitis and, 425
Plasmodium infections causing, 1343
in pneumonia, 241
prolonged, in acute bacterial meningitis, 286, 286*b*
prolonged insignificant, 121–122, 122*b*
rabies virus causing, 1177–1178
recurrent, 122, 123*f*
relapsing infections causing, 122
resolved, prolonged illness with, 121–122, 122*b*
Rickettsia prowazekii (epidemic typhus) causing, 958
Rickettsia rickettsii (Rocky Mountain spotted fever) causing, 953

  - *Rickettsia typhi* (murine typhus) causing, 959
  - sepsis and, 100
  - *Streptobacillus moniliformis* causing, 966
  - subdural empyema and, 332
  - *Trichinella spiralis* infections causing, 1387
  - *Trypanosoma (Trypanozoon) brucei* infection causing, 1368
  - *Trypanosoma cruzi* infection causing, 1371
  - of unknown origin (FUO), 117–121
    - approach to workup, 119–121, 120*t*–121*t*
    - definition, 117–118, 118*f*
    - diagnostic clues, 117–118
    - duration, 117–118
    - etiology, 118–119, 119*b*, 119*t*
    - noninfectious causes of, 119*b*
  - varicella and, 1067
  - in viral upper respiratory tract infections, 230
  - visceral leishmaniasis causing, 1328–1329
  - without localizing signs, 115–117
    - epidemiology of, 115–116
      - children older than 3 months, 116
      - children younger than 3 months, 115–116
    - etiologic agents of, 115, 115*t*
    - laboratory findings and diagnosis of, 116
    - management of, 116–117
      - children 3 months of age and older, 117
      - children younger than 3 months, 116–117
      - other considerations, 117
- Fibrinogen, synthesis, in *Enterococcus faecalis*, 730

Fibromyalgia syndrome, 188
  - *Mycoplasma* infection and, 1029–1030

Fibrosis, congenital hepatic, 412

Filarial dance sign, 1389

Filarial infections (filariasis), 1388
  - chronic sequelae of, 1389
  - lymphatic, 1389–1391, 1389*b*
    - clinical manifestations of, 1389–1390, 1389*f*
    - epidemiology of, 1389
    - laboratory findings and diagnosis of, 1390, 1390*f*, 1390*t*
    - prevention of, 1391
    - special considerations to, 1391
    - treatment of, 1390–1391
  - treatment for, 1570

Filarial worms, 1388–1394
  - characteristics of, 1388*t*

Filoviridae, 1045*t*
  - infections, 1046*t*

Filoviruses, 1190–1195, 1195*b*
  - aerosol transmission of, 1190
  - clinical laboratory findings of, 1192, 1193*t*
  - clinical manifestations of, 1192–1193, 1192*f*
  - contact tracing for, 1195
  - differential diagnosis of, 1193
  - epidemiology of, 1190
  - hospital discharge and management of convalescence in, 1194
  - human-to-human transmission of, 1190
  - laboratory testing for, 1193

  lymphocytic choriomeningitis virus, 1192–1193, 1194*f*
  maintenance in nature of, 1190
  pathobiology of, 1190–1192
  personal protection and nursing precautions for, 1195
  postexposure prophylaxis for, 1195
  prevention of, 1195
  reservoir and vector control for, 1195
  transmission to humans of, 1190, 1191*t*
  treatment of, 1193–1194
  vaccines for, 1195
  viral hemorrhagic fever and, 1192
Finafloxacin, treatment for, ear infections, 1545*t*
Fine crackles, 171
Finegoldia, 1018
Fish
  cooking of, in preventing *Diphyllobothrium* infection, 1395
  diseases associated with, 539
  in *Heterophyes* transmission, 1412–1413
  raw, visceral larva migrans after consuming, 1385
Fitz-Hugh-Curtis syndrome (acute perihepatitis), 765
  Chlamydia trachomatis from, 911
  peritonitis and, 424
Flagella, *Pseudomonas aeruginosa* and, 866–867, 867*t*
Flank pain, renal abscess and, 346
Flavimonas oryzihabitans (Pseudomonas oryzihabitans), 865, 865*t*
Flaviviridae, 1045*t*
  arthritis from, 491*b*
  infections, 1046*t*

Flaviviruses, 1128–1132

  diagnosis of, 1131

  key points in, 1132*b*

  of medical importance, 1131

  prevention of, 1131

  specific agents in, 1128–1131

    dengue viruses, 1129

    Japanese encephalitis virus, 1129–1130

    tickborne encephalitis virus, 1130

    West Nile virus, 1130

    yellow fever virus, 1128

    Zika virus, 1130–1131

, Flavobacteriaceae, 856

Flavobacterium breve (Empedobacter brevis), 856

Flea, *Dipylidium caninum* and, 1395

Flea bites, 540

Flea-borne typhus, 959–960

Flora, normal

  cancer and, 580

  Capnocytophaga spp., 905

  gastrointestinal

    Enterobacter, 825

    Proteus, Providencia and *Morganella*, 833–834

  indigenous, 988–990

    role of, 988–990

  mouth, *Lactobacillus*, 788

  normal, establishment and composition of, 988

  oral cavity, *Actinobacillus actinomycetemcomitans* in, 967

  of skin, 528
Flow cytometry
  for acute bacterial meningitis diagnosis, 282–283
  for *Cyclospora*, 1322
Fluconazole, 1536–1537
  adverse effects of, 1536, 1584
  clinical experience of, 1536–1537
  dosing of, 1490*t*–1498*t*
  pediatric data of, 1536–1537
  pharmacology of, 1536
  toxicities of, 1536
  treatment for
    Acanthamoeba infections, 1341
    Blastomyces dermatitidis (blastomycosis), 1273
    Candida infections, 1236–1237
    Coccidioides immitis (coccidioidomycosis), 1280
    Cryptococcus infection, 1258
    dermatophyte infections, 356
    endocarditis, 268
    Histoplasma capsulatum, 1265
    Naegleria fowleri, 1338
    Sporothrix schenckii, 1254–1255
    tinea capitis, 1284
    tinea versicolor, 1286
Flucytosine (5-fluorocytosine), 1536
  adverse effects of, 1584
  clinical experience of, 1536
  dosing of, 1490*t*–1498*t*

  mechanism of action, 1536
  pediatric data of, 1536
  pharmacology of, 1536
  toxicities of, 1536
  treatment for
    Acanthamoeba infections, 1341
    Candida infections, 1236
    Cryptococcus infection, 1258
Fluid restriction, in acute bacterial meningitis, 286
Fluid resuscitation
  for *Shigella* infections, 844
  for *Vibrio cholerae* infection, 876, 877*t*
Flukes
  in liver, 1415
  praziquantel for, 1571
Fluorescent antibody against membrane antigen (FAMA), 1441
Fluorescent antibody test
  for spirochetes, 1433
  for viral infection diagnosis, 1434
Fluorescent treponemal antibody-absorbed test (FTA-ABS), 972
Fluorodeoxyglucose positron-emission tomography (FDG-PET)
  for fever of unknown origin (FUO), 119–121
  for granulomatous hepatitis, 418
Fluoroquinolones, 1523–1524
  dosage for, 1527*t*–1530*t*
  pharmacokinetics of, 1499*t*–1505*t*
  resistance to
    anaerobic cocci, 1019

    - *Clostridium difficile*, 388
    - *Clostridium difficile* and, 1007
    - *Klebsiella*, 821
    - *Neisseria gonorrhoea*, 766*b*
    - *Proteus mirabilis*, 834
    - *Salmonella choleraesuis*, 839
    - *Salmonella* Typhi, 839
  - spectrum of activity of, 1506*t*–1511*t*
  - treatment for
    - acute bacterial meningitis, 283
    - bacterial keratitis, 508
    - bite wound infections, 536
    - *Campylobacter jejuni* infections, 904
    - *E. coli* diarrheal infections, 818
    - endophthalmitis, 515–516
    - extracellular infections, 1464
    - intracellular infections, 1464
    - *Mycoplasma hominis*, 1029
    - *Mycoplasma pneumoniae* infection, 1026
    - urinary tract infections, 345
    - *Yersinia pestis*, 849–850, Quinolones
- Focal bacterial nephritis, as complications of urinary tract infection, 346
- Focal intestinal perforation
  - in necrotizing enterocolitis, 395
  - neonatal, coagulase-negative staphylococci (CoNS) causing, 709
- Folate metabolism inhibitors, protozoan infection treatment for, 1570

Folliculitis, 437*t*, 439–440, 440*f*
  Enterobacter causing, 440
  Escherichia coli causing, 440
  hot tub, 437*t*, 440
  Klebsiella causing, 440
  Malassezia, 1252
    acne vulgaris *vs*., 1252
  Malassezia furfur causing, 440
  Pseudomonas aeruginosa causing, 440, 868*t*
  Staphylococcus aureus causing, 440
Fontanel, bulging, human herpesvirus 6 causing, 1083
Food(s)
  raw, safety measures for, 408
  Shigella and, 843
Food and Drug Administration (FDA) licensure, 46
Food handlers, norovirus infection prevention, 1223
Food poisoning, staphylococcal, 701
Food vacuole, *Plasmodium* and, 1343
Foodborne disease, 379, 379*t*, 398
  Bacillus cereus causing, 398, 772
  Campylobacter causing, 398
  Campylobacter jejuni causing, 406
  clinical syndromes of, 406
  complications of, 408
  diagnosis of, 407

p24 antigen, detection tests for, 1444
Pneumocystis jirovecii pneumonia prophylaxis and, 680, 680*b*
pneumonia from, 677–678
prevention of, 679–680
prognosis of, 673–674, 674*f*, 681
progressive multifocal encephalopathy from, 678, 678*f*
Pseudomonas aeruginosa in, 868*t*
pulmonary conditions of, 688
renal health and, 687
reproductive health in, 688–689
reverse transcriptase inhibitors, 681–683
Rhodococcus (Corynebacterium) equi infections and, 787
rubella-containing vaccine, 1147
Salmonella gastroenteritis in, 839
screening for, 1444
Shigella infections in, 844
subtype B, diagnosis of, 668
subtype C, diagnosis of, 668
suspected systemic, or focal infection, child with, 676–679
syphilis and, 970–971
transition of, 689
transmission of, bite wounds causing, 535
Trypanosoma cruzi and, 1372
type 1, 1198–1199, 1198*t*
type 2, 1198*t*, 1199
vaginitis and, 365
viral load, measurement of, 1444
wasting syndrome and, 670*b*, 672

Human metapneumovirus (hMPV), 1165–1169, 1168*b*
  bronchiolitis from, 234
  clinical manifestations of, 1167, 1167*b*, 1168*t*
  description of, 1165–1167, 1166*f*
  diagnosis/detection of, 1442
  epidemiology of, 1167
  genes and proteins of, 1166*t*
  laboratory findings and diagnosis of, 1167
  laboratory testing of, 318*t*–321*t*
  optimal tests for, 1437*t*–1440*t*
  pathologic features of, 1166–1167
  pneumonia from, 238–239
  special considerations of, 1167–1168
  treatment of, 1167
Human microbiome, role of, in health and disease, 990
Human monkeypox, 538
Human monocytic ehrlichiosis
  agents, vectors, and geographic distribution of, 543*t*
  clinical and laboratory manifestations of, 544*t*–545*t*
Human papillomavirus (HPV), 195*t*, 1101–1105
  anogenital cancers from, 1102–1103
  anogenital tract infections from, 1102
  anogenital warts from, 1103
    treatment for, 1104*b*
  antibodies to, 1102
  antigens to, 1101
  cervical cancer and
    in HIV-infected women, 1102

  prevention for, 1104
in child abuse, 375
clinical features of, 1102–1103
cutaneous warts from, 1103
description and structure of, 1104*b*
diagnosis for, 1103, 1104*b*
E6 and E7 proteins of, 1101
epidemiology of, 1102–1103, 1105*b*
epidermodysplasia verruciformis from, 1103
epitheliotropic, 1101
exanthems from, 446*b*
HPV-6, 1102
HPV-11, 1102
HPV-16, 375, 1102
HPV-18, 375, 1102
in immunocompromised individuals, 1103
laryngeal papillomas from, 352
management of, 1103–1104
optimal tests for, 1437*t*–1440*t*
oral infections and cancers of, 1103
pathogenesis of, 1101–1102
prevention for, 1104, 1104*b*–1105*b*
recurrent respiratory papillomatosis, juvenile, 1103
screening of, 1103, 1105*b*
subtypes, in child abuse, 375
treatment for, 1105*b*, 1557–1558
vaccine for, 69, 352–353
vulvovaginitis from, 360

Human parechovirus(es), 1200
  aseptic meningitis from, 301–303
  encephalitis from, 310–311
  pneumonia from, 238–239
Human parvoviruses, 1115–1119
Human polyomaviruses, 1105–1107
  dissemination of, 1106
  epidemiology of, 1105–1106
  KI polyomavirus, 1105–1107
  Merkel cell virus and, 1105–1107
  trichodysplasia spinulosa-associated polyomavirus, 1105–1107
  Wu polyomavirus, 1105–1107
Human rabies immune globulin, 39
Human T-lymphocyte lymphotropic viruses (HTLV), 1197–1198, 1197*b*
  clinical manifestations of, 1197
    HTLV-1, 1197
    HTLV-2, 1197
  epidemiology of, 1197
  HTLV-1, *Strongyloides stercoralis* infections causing, 1379
Human-to-human transmission, of Ebola Zaire virus, 1190
Human viruses, classification of, 1044–1048
Humoral immune response, 618
  in HIV infection, 675
  in HSV infections, 1056–1057
  parainfluenza viruses and, 1153
Hyalohyphomycosis
  agents causing, 1244–1245

  clinical manifestations of, 1245, 1247*b*
  diagnosis of, 1245, 1247*b*
  epidemiology of, 1245, 1247*b*
  laboratory evaluation of, 1245
  microbiology of, 1247*b*
  therapy and prevention of, 1245, 1247*b*
Hyalomma ticks, as vector, of *Rickettsia prowazekii*, 958
Hybrid study design, 2
Hydatid disease, 1293, 1293*t*
Hydration, for bronchiolitis, 237
Hydrocephalus
  acute, after acute bacterial meningitis, 287
  congenital toxoplasmosis causing, 1355
  obstructive
    in meningitis, 280
    Taenia solium neurocysticercosis causing, 1401
Hydrogenosomes, 1364
Hydronephrosis, 346
Hydrophobia, rabies virus causing, 1177–1178
Hydrops fetalis, parvovirus B19 causing, 1116*t*, 1118
Hydroxychloroquine
  for *Coxiella burnetii* infections, 917–918
  for *P. falciparum*, 1572
  for *P. malariae or P. knowlesi*, 1572
  for *P. vivax* or *P. ovale*, 1572
  for *Plasmodium* infections, 1345*t*–1346*t*, 1347, 1348*t*
    prophylaxis, 1345*t*–1346*t*, 1347
  for uncomplicated malaria, 1572

Hygiene, for *Vibrio cholerae* infection protection, 878

Hymenolepis diminuta, 1293*t*

- infection from, 1395–1396
    - clinical manifestations of, 1396
    - description of, 1395
    - epidemiology of, 1395–1396
    - laboratory findings and diagnosis of, 1396
    - prevention of, 1396
    - treatment of, 1396

Hymenolepis nana, 1293*t*

- infection from, 1395–1396
    - clinical manifestations of, 1396
    - description of, 1395
    - epidemiology of, 1395–1396
    - laboratory findings and diagnosis of, 1396
    - prevention of, 1396
    - treatment of, 1396

Hyper-IgM syndrome, in *Pneumocystis jirovecii (carinii)* infections, 1267

Hyperbaric oxygen

- for *Clostridium perfringens* gas gangrene, 1011
- for mucormycosis, 1249

Hypercalcemia, in *Histoplasma capsulatum* infections, 1261

Hyperemia, conjunctival, 501

Hypereosinophilic syndrome, definition of, 1454

Hypergammaglobulinemia, of HIV infection, 255, 675

Hyperglycemia, 1458

- *Vibrio cholerae* infection causing, 876

Hyperimmune serum, for *Bordetella pertussis*, 897

Hyperimmunization, for *Clostridium tetani* prevention, 999

Hyperimmunoglobulin E-autosomal dominant syndrome, 640*t*, 641

Hyperimmunoglobulin E-autosomal recessive syndrome, 640*t*, 641

Hyperimmunoglobulin E-recurrent infection syndrome, 629*t*–630*t*, 634

Hyperimmunoglobulin M syndrome, 619*t*, 622, 622*b*, 640*t*, 641

, Hyperimmunoglobulinemia D syndrome (HIDS), 125

Hyperkalemia, 1568

Hypersplenism, 1457

Hyperthermia, fever and, 94

Hyperthyroidism, generalized lymphadenopathy from, 135

Hypnozoite, of *Plasmodium*, 1342–1343

Hypogammaglobulinemia

- *Mycoplasma pneumoniae* infection and, 1025
- *Neisseria meningitidis* in, 749
- transient, of infancy, 619*t*, 623–624, 624*b*

Hypoglycemia, 1458

- *Plasmodium* infections causing, 1344
- *Shigella* infection causing, 844
- *Vibrio cholerae* infection causing, 876

Hypokalemia, *Vibrio cholerae* infection causing, 876

Hyponatremia, 1458

- Rocky Mountain spotted fever *(Rickettsia rickettsii)* and, 955
- *Shigella* infection causing, 844

Hypopigmentation, varicella lesions and, 1066–1067

Hypopyon, 515, 515*f*

Hypotension

  chronic fatigue syndrome causing, 1039
  infection after burns and, 527
Hypothalamic-pituitary axis (HPA) abnormalities, chronic fatigue syndrome causing, 1039
Hypothermia, infection after burns and, 527
Hypothyroidism, infant botulism *versus*, 1003*t*
Hypotonia, 182–184
  in infants, features of causes of, 182*t*–183*t*
Hypovolemia, *Vibrio cholerae* infection causing, 876
Hypoxemia
  in bronchiolitis, 236
  in pneumonia, 243
Hyrtl fissure, 297

I

Ibuprofen, for transient synovitis, 497
Idiopathic thrombocytopenic purpura (ITP), 1458
  Helicobacter pylori infection and, 938
Ileitis
  hookworm causing, 1377
  terminal
    Yersinia enterocolitica infections and, 131
    Yersinia pseudotuberculosis infections and, 131
  Trichuris trichiura causing, 1378
  Yersinia enterocolitica causing, 847
Ileocolitis, eosinophilic, *Enterobius vermicularis* causing, 1379
Iliopsoas abscess, 697
  etiology of, 432

Imaging
  for acute bacterial meningitis diagnosis, 283
  for myocarditis, 272
  for sinusitis, 231–232
Imidazole, for *Malassezia* infections, 1252
Imipenem
  dosing of, 1490*t*–1498*t*
  treatment for, eye infections, 1544*t*
Imipenem-cilastatin
  dosage for, 1527*t*–1530*t*
  pharmacokinetics of, 1499*t*–1505*t*
  spectrum of activity of, 1506*t*–1511*t*
Immediate hypersensitivity reactions, to basophils, 1457
Immigrants, immunization for, 56
Immortalization, 1089
Immune complexes
  deposition of, *Neisseria meningitidis* infections and, 755
  in urticaria pathogenesis, 459
Immune consequences, of HIV-1 infection, 666, 666*b*–667*b*
Immune deficiencies, in HSCT recipients, 573
Immune dysfunction, chronic fatigue syndrome causing, 1039
Immune dysregulation disorders, granulomatous hepatitis and, 418
Immune globulin (human), 37–38
  for *Cryptosporidium* infections, 1308
  for hepatitis A, 38
  for hepatitis A virus infection prevention, 1217
  intramuscular administration of, 38–39
  intravenous administration of, 37*t*, 41

for measles, 38
  for pneumonia, in immunocompromised host, 261
  for rubella, 38
  for varicella-zoster, 1071
Immune globulin intravenous (IGIV), 38*t*, 39–41, 184
  for acute disseminated encephalomyelitis, 326
  approved indications of, 40–41, 40*t*
  for aseptic meningitis, 304
  for *Clostridium tetani*, 997, 997*t*
  for enterovirus infections, 1206, 1212–1213
  immunomodulation by, 40–41
  for Kawasaki disease, 1035–1036
    indications of, 114
  for myocarditis, 273
  for necrotizing fasciitis, 479
  for primary immune deficiencies, 40
  for secondary immune deficiencies, 40
Immune-mediated cytopenias, 41
Immune reconstitution inflammatory syndrome (IRIS)
  ART effect in *Cryptococcus* infections, 1258
  HIV infection and, 675–676
  nontuberculosis *Mycobacterium* species and, 810
Immune response, rubeola virus and, 1169–1170
Immune serum globulin, antiviral therapies, for aseptic meningitis, 304
Immune status, as risk factors, in urinary tract infections, 344
Immune system
  adaptive, 95–96, 95*f*

  - innate, 95–96, 95*f*
  - in recurrent meningitis, 296
- Immune thrombocytopenic purpura, 40
- Immunization (active), 43–71
  - antibody-containing products and vaccines, spacing of, 50
  - bacille Calmette-Guérin vaccine, 69–70
  - benefits of, 43
  - before biologic response modifier therapy initiation, 653–654
  - clinical practice guidelines, for child and adolescent, 57–58
  - contraindications and precautions, 61
  - cost benefits of, 43
  - definitions of, 43–44
  - diphtheria and tetanus toxoids and pertussis vaccines, 59–60, 59*t*
  - *Haemophilus influenzae* type b conjugate vaccines, 60–61
  - hepatitis A vaccine, 66
    - contraindications and precautions, 66
    - recommendations for, 66
  - hepatitis B vaccine, 61–62
    - contraindications and precautions, 62
    - recommendations of, 61–62, 61*t*
  - for HSCT recipients, 577, 577*t*
  - human papillomavirus vaccine, 69
    - contraindications and precautions, 69
    - recommendations for, 69
  - for immigrants, 56
  - immunity induced by vaccination, 44
  - influenza vaccines, 66–67
    - contraindications and precautions, 67

  recommendations for, 66–67
interchangeability of vaccines, 50–51
for international adoptees, 33, 36–37, 36*t*, 56
for international travelers, 56
for low-birthweight infants, 53–55
measles, mumps, and rubella vaccine, 62–64
  contraindications and precautions, 63–64
  recommendations for, 62–63
meningococcal vaccines, 67–68
  precautions and contraindications, 68
  recommendations for, 67–68
for neutropenia associated with cancer, 585
passive, Passive immunization
pneumococcal conjugate and polysaccharide vaccines, 64
  contraindications and precautions, 64
  recommendations for, 64
polio vaccines, 64–65
  contraindications and precautions, 65
  recommendations for, 65
for pregnant women, 55
primary, 45
program, principles of, 46–59
  disease reduction, 46, 47*t*
  immunization coverage, 46–47
  vaccine administration, 47–50
programmatic issues in, 56–57
recommendations for, 60–61
for refugee children, 36

rotavirus vaccine, 68–69
  contraindications and precautions, 69
  recommendations for, 68–69
routine childhood and adolescent vaccines, 59–69
for rubeola virus, 1174–1175
simultaneous administration of, 47
Tdap, for adolescents, 11 through 18 years of age, recommendations for, 60
for travelers, 70
  cholera vaccine, 70
  Japanese encephalitis vaccine, 70
  typhoid fever vaccine, 70
  yellow fever, 70
vaccination in special situations, 53–56
vaccine development, licensure, and approval in, 44–46
  administration, sites of, 45
  determinants of response, 45
  host factors, 45
  immune response to, 44–45
  immunologic basis of response to vaccines, 44
  licensure and approval, 46, 46*f*
  response, measurement of, 45–46
vaccine financing, 58, 58*t*
vaccine-preventable diseases, surveillance for, 59
vaccine safety
  compensation for vaccine injury, 51–53, 52*t*
  compensation program for adverse events after immunization, 53

    - monitoring of, 53
    - studies of, 51–53, 54*t*, 55*b*
  - vaccine shortages, 58
  - vaccine spacing, 47
  - vaccines, 43–44
    - content of, 44
  - varicella vaccine, 65–66
    - contraindications and precautions of, 66
    - recommendations for, 65–66, *see also individual vaccines*
- Immunoassay, optical, for group A *Streptococcus*, 1426
- Immunocompromised children
  - herpes zoster in, 1069
  - parvovirus B19 in, 1118*b*
  - VZV infection in, 1068
- Immunocompromised hosts
  - adenoviruses infections in, 1098*t*, 1100
  - animal bite infections and, 534
  - *Aspergillus* species in, 1238
  - babesiosis in, 1298–1300
  - *Balantioides coli* infections in, 1303
  - *Bartonella* species and, 885
  - *Cryptosporidium* infections in, 1307
  - *Cyclospora cayetanensis* in, 1321
  - diarrhea in, 392, 392*b*
  - of *Histoplasma capsulatum* (Histoplasmosis), 1261, 1262*f*
  - immunization for, 55–56, 56*t*–57*t*
  - inflammatory enteritis in, 392
  - of influenza viruses, 1186

  Lactobacillus infections in, 788
  Legionella pneumonia in, 949
  Pseudomonas aeruginosa in, 870
  Pseudomonas in, 865
  rubeola virus infection (measles) in, 1173
  Salmonella infection in, 840
Immunodeficiency
  drug-induced, 258
  enteroviral infections and, 1213
  Giardia intestinalis (giardiasis) and, 1318
  immunization for, 55–56
  involving antibody deficiency, 619*t*
  mucosal, respiratory tract infections and, 258
  Mycoplasma pneumoniae infection and, 1024
  primary, 613–614, 614*b*
    characteristics of, 614*b*
    frequency of, 613–614, 614*t*
    genetic testing for, 617
    , screening tests for, 616*t*
    specific testing for, 616–617, 617*t*
  sentinel pathogens and, 615*t*
  structural abnormalities with, pneumonia from, 258
  suspected, evaluation of child with, 613–617
    abnormalities associated with, 613, 613*t*
    conditions predisposing, 613, 614*b*, Recurrent infections
  varicella and, 1068
  VZV infections and, 1066, 1068
Immunodiffusion complement fixation (IDCF) test, for *Coccidioides*

  - *immitis* (coccidioidomycosis), 1280

- Immunodiffusion precipitin test, for *Histoplasma capsulatum*, 1263
- Immunofluorescence staining/assays
  - for Colorado tick fever virus, 1121
  - for *Ehrlichia* and *Anaplasma* infections, 921
  - for HIV, 669*t*
  - for HSV infections, 1062
  - for *Trypanosoma cruzi*, 1372
  - for VZV detection, 1069
- Immunoglobulin(s)
  - deficiency
    - isotype, 619*t*, 622–623
    - persistent or recurrent pneumonia and, 255
  - heavy chain deficiency, 622
  - predominant pathogens infecting children with, 580*t*
  - products, prepared from animal plasma, 42
- Immunoglobulin A (IgA)
  - in common variable immunodeficiency disorder, 621
  - deficiency, 619*t*, 623
    - with IgG subclass deficiency, 619*t*, 622*b*, 623
  - *Entamoeba histolytica* infection and, 1312
  - *Haemophilus influenzae* producing, 927
  - in respiratory tract, 258
  - secretory
    - deficiency, *Giardia intestinalis* (giardiasis) and, 1318
    - enterovirus infections and, 1206
  - *Toxoplasma gondii* infection and, 1356–1357
- Immunoglobulin (Ig) A1 protease, 748

Immunoglobulin E (IgE)
  - *Toxoplasma gondii* infection and, 1356
  - in urticaria pathogenesis, 456

Immunoglobulin G (IgG)
  - anti-VZV, 1441
  - antifilarial, 1389
  - arboviruses and, 1445
  - for *Borrelia burgdorferi*, 983
  - *Chlamydia trachomatis* and, 1446
  - CMV and, 1441
  - in common variable immunodeficiency disorder, 621
  - in congenital rubella, 1143, 1143*f*, 1146
  - EBV and, 1441–1442
  - *Giardia intestinalis* (giardiasis) and, 1318
  - hepatitis A virus and, 1443
  - hepatitis E virus and, 1443
  - HHV-6 and, 1442
  - HSV and, 1441
  - for HSV infection, 1062
  - measles, mumps, and rubella and, 1444
  - *Mycoplasma pneumoniae* and, 1446
  - parvovirus B19 and, 1115, 1118, 1445
  - subclass deficiency, 619*t*, 622–623, 622*b*
    - IgA deficiency with, 619*t*, 622*b*, 623
  - *Toxoplasma gondii* infection and, 1356
  - in urinary tract infections, 344
  - viral infection diagnosis and, 1434, 1436
  - for VZV infection, 1069

Immunoglobulin M (IgM)
  for *Borrelia burgdorferi*, 983
  Chlamydia trachomatis and, 1446
  CMV and, 1441
  for *Coccidioides immitis* (coccidioidomycosis), 1280
  in common variable immunodeficiency disorder, 621
  in congenital rubella, 1143, 1143*f*, 1147
  in flavivirus infections, 1131
  Giardia intestinalis (giardiasis) and, 1318
  for hepatitis A virus, 1216, 1443
  hepatitis E virus and, 1443
  HHV-6 and, 1442
  for HSV infection, 1062
  human herpesvirus 6 (HHV-6) and, 1442
  human herpesvirus 8 (HHV-8) and, 1442
  for *Listeria monocytogenes* opsonization, 782–783
  measles, mumps, and rubella and, 1444
  Mycoplasma pneumoniae and, 1446
  parvovirus B19 and, 1115, 1118, 1445
  response during viral infections and, 1436*f*
  Toxoplasma gondii infection and, 1356
  viral infection diagnosis and, 1434
  virus-specific, 1434, 1436
    false-negative/positive, 1436
  for VZV infection, 1069
Immunohistochemical staining, for diagnosis, of *Rickettsia rickettsii*, 955
Immunologic abnormalities, persistent or recurrent pneumonia

  and, 255
Immunology, of chronic fatigue syndrome, 1039
Immunoserology, in laboratory diagnosis, 1433
Immunosuppression
  in burn patients, infections after, 528
  for hemophagocytic lymphohistiocytosis, 106–107
  posttransplant lymphoproliferative disease (PTLD) after, 1092
  in risk for infection after transplantation, 567
Impetigo, 437–438, 437*t*
  bullous, 437, 438*f*
  nonbullous, 437
  secondary infections in varicella and, 1067
  Staphylococcus aureus causing, 437, 695, 695*f*
  Streptococcus pyogenes causing, 438
  treatment for, 1546
Incidence, 1–2
Incidence density, 1
Inclusion(s)
  intranuclear, of CMV, 1441
  viral, in viral pneumonia, 240
Indinavir (IDV), 682*t*, 1490*t*–1498*t*
Indirect hemagglutination antibody assay
  for *Burkholderia pseudomallei*, 872
  for *Echinococcus granulosus*, 1406
  for *Entamoeba histolytica*, 1314
  for *Trypanosoma cruzi*, 1372
Indirect immunofluorescence antibody (IFA) assay
  for *Babesia* (babesiosis), 1300

for *Cryptosporidium*, 1307

for *Legionella*, 951

for *Rickettsia prowazekii*, 959

for *Rickettsia rickettsii*, 955

Indwelling vascular catheters, infection, *Staphylococcus aureus* causing, 701

Infant(s)

botulism, 182*t*–183*t*

bronchiolitis in, 234

enterovirus infections in, 1207

hypotonia causes in, 182*t*–183*t*

Kawasaki disease course in, 114

myocarditis in, 272

pneumonia in, 170*t*, 171, 238–240

progressive disseminated histoplasmosis in, 1261, 1262*f*

pyogenic arthritis in, 185

respiratory syncytial virus and, 1163

RSV bronchiolitis in, 234–236

urinary tract infections in, 344

Infantile hypertrophic pyloric stenosis, after *Chlamydia trachomatis* infection treatment, 912

Infantile seborrheic eczema (ISE), *Malassezia* causing, 1252

Infection

Bartonella henselae causing, 130

burns and, 527–532

Chlamydia trachomatis from, 911

Francisella tularensis causing, 130

HIV, in children and adolescents, 659–665

- clinical manifestations of, 660
- epidemiology of, 659–660, 659*t*
- prevention of, 660–665
- progression of, 660

HIV-1, immunopathogenesis of, 665–667
- antiviral therapy for, 666–667
- immune consequences of, 666, 666*b*–667*b*
- replication of, 665–666

immunologic development and susceptibility to, 85–93

laboratory diagnosis of, due to bacteria, fungi, parasites, and rickettsiae, 1422–1434

of skin
- primary, 466
- secondary, 466

Infection-associated hemophagocytic syndrome, 1094

Infection prevention and control (IPC)
- definition of, 13
- in nonacute care setting, 20–25

Infectious agents, transmission of, 42–43

Infectious arthritis, 487–490

Infectious diseases
- acute phase response in, 1447, 1447*b*
- laboratory manifestations of, 1447–1459

Infectious mononucleosis
- clinical aspects of, EBV, 1089–1092
- diagnosis of, 1441

Infectious mononucleosis (IM)-like syndrome, adenoviruses and, 1098*t*, 1100

Infertility, pelvic inflammatory disease and, 369
Inflammasome, 45, 127
Inflammatory arthritis, 487–493
Inflammatory bowel disease (IBD)
  E. coli causing, 817–818
  Helicobacter species and, 943
  Salmonella gastroenteritis in, 839
Inflammatory mediators, infection after burns, 527
Inflammatory response, 94–97
  acute phase of, 96–97
  in *Enterobius vermicularis* infections, 1379
  eumycotic mycetoma and, 1288
  of peritoneum, 423
  regulatory anti-inflammatory pathways in, 97
  Trypanosoma cruzi infections and, 1371
Infliximab, for TRAPS, 127
Influenza-associated myositis (IAM), 475
Influenza virus(es), 73*t*–74*t*, 75, 1181–1190, 1189*b*
  antigenic drift in, 1181–1182
  antigenic shift in, 1181–1182, 1189
  antigenic types of, 1181
  2009 A(H1N1)pdm09 pandemic, 1183
  avian influenza A H5N1 virus, 1188
  bronchiolitis from, 234
  chemoprophylaxis for, 1188
  clinical manifestations of, 1183–1184, 1183*t*
  complications of, 1184
  diagnosis/detection of, 1184–1185, 1185*t*, 1442

    antigen detection for, 1442
    sample collection for, 1442
epidemiology of, 1183
in group childcare, 28–29
H1N1, 1182, 1182*f*
H3N2, 1183
higher risk for complications, 1186, 1186*b*
human immunodeficiency virus coinfection, 1186
immunity to, 1183
immunocompromised hosts of, 1186
laboratory findings of, 1184
laboratory testing of, 318*t*–321*t*
microbiology of, 1181–1182, 1181*f*
optimal tests for, 1437*t*–1440*t*
pandemics, 1189
    of 20th and 21st centuries, 1182
pathogenesis of, 1182–1183
pneumonia from, 238–239
pregnancy and, 1186–1187
prevention of, 1187–1188
seasonal influenza on children of, 1183
special considerations in, 1186–1187
standard convention for, 1181, 1182*b*
swine, 1182, 1189
transmission of, 11
treatment for, 1185–1186, 1565
    adamantanes, 1185
    indications for, 1186

    - in infants, 1186
    - neuraminidase inhibitors, 1185–1186
    - resistance in, 1186
  - type A, treatment of infection for, 1566
  - type B, treatment of infection for, 1566
  - vaccine for, 66–67, 1187
    - for children with egg allergies, 1187
    - inactivated, 1187–1188
    - live, attenuated, 1188
  - zoonotic, 1188–1189

, Infusion-related reactions, to immune globulins, 42, 42*b*

Inhalation injuries, 529

Inherited immunodeficiency syndromes, generalized lymphadenopathy from, 134

Inhibitory mold agar (IMA), 1431

Injection drug use, in HCV, 1136–1137

Injuries, Trauma

Innate immune response, 45, 86–89
  - activation of, in sepsis, 100
  - adaptive immune response, 89–93, 90*f*
  - antimicrobial products, skin, and mucosal barriers, 86
  - B lymphocytes, 89–92, 90*f*
  - complement, 88–89
  - dendritic cells, 87–88
  - interrelationships and future of, 93
  - natural killer cells, 89, 89*t*
  - parainfluenza viruses and, 1152–1153
  - pathogen receptors and toll-like receptors, 86–87

  phagocytes, 87, 88*f*
  T lymphocytes, 90*f*, 92–93, 92*t*
  VZV infections and, 1065
Innate immune system, 95–96
  interaction of, 97
  receptors of, 96
Innate lymphocyte cells (ILCs), 636
Inner-ear malformation, in recurrent meningitis, 296
Inoculation mycoses, 1230, 1230*t*
Inoue-Melnick virus, chronic fatigue syndrome from, 1038*b*
InPouch culture system, 358–359
InPouch TV, culture system, 1365
Insect repellents, for *Borrelia burgdorferi* infection prevention, 985
Insecticides, for *Trypanosoma (Trypanozoon) brucei* infection prevention, 1369
Institute of Medicine (IOM), in immunization safety review, 53
Integrase inhibitors, 683
Integrase strand transfer inhibitors, 682*t*
Integrons, in acquired drug resistance, 1469
Intensive care units (ICUs), central line-associated bloodstream in, infections, 12
Intent-to-treat analyses, 9
Interference, with active immunization, 42
Interferon (IFN), in chronic HCV infection, 1141
Interferon *α*, for myocarditis, 273
Interferon *α*/β, VZV infection and, 1065
Interferon *α*-n3, for West Nile virus, 1130
Interferon β, for myocarditis, 273

Interferon γ receptor deficiency, 640*t*

Interferon γ release assay (IGRA)

  for diagnosis of pneumonia, 243

  for HIV infection, 677

  for *Mycobacterium tuberculosis*, 800

  for nontuberculosis *Mycobacterium* species, 808

Interim analysis, 6

Interleukin(s), infection after burns, 527

Interleukin-6 (IL-6), sepsis and, 1450–1451

Interleukin-8 (IL-8)

  chemoattractant for neutrophils, 200

  gut ischemia and, 1451

Interleukin-12 receptor chain deficiency, 640*t*

Interleukin-17 pathway disorder, 640*t*

Internalin, *Listeria monocytogenes* virulence factor, 782

International Committee on Taxonomy of Viruses (ICTV), 1044–1045

International travelers, immunization for, 56

Interpretation, of study, 9

Interquartile range, 5

Intertrigo, 437*t*, 438–439, 439*f*

Intervertebral disk, composition of, 494

Intervertebral disk space

  aspiration of, 495

  blood supply to, 494

Intestinal amebiasis (amebic colitis), Amebic colitis (intestinal amebiasis)

Intestinal biopsy, for inflammatory enteritis, 391–392

Intestinal flagellates, 1316–1317

Intestinal flukes, 1293

Intestinal nematodes, Nematodes (roundworms)

Intestinal obstruction, *Ascaris lumbricoides* causing, 1374–1375, 1375*f*

Intestinal perforation

- hospital-associated infection causing, 561
- *Salmonella* Typhi infection and, 841

Intestinal schistosomiasis, 1419

Intestinal stricture, *Entamoeba histolytica* infection causing, 1313

Intestinal transplantation, infections after, 569

Intestinal trematodes, 1412–1413, 1412*t*

Intimin, 816

Intra-abdominal abscesses, 432–434, 433*t*, 436*b*

- clinical manifestation of, 432–433
- etiology of, 432–433
- management of, 433–434, 434*f*
- percutaneous drainage for, 433
- postoperative, 433, 433*f*

Intra-abdominal infections

- anaerobic cocci causing, 1019
- in burn patients, 530
- cancer and, 590–591
- viridans streptococci causing, 734, *see also individual infections*

Intracellular infections, antimicrobial therapy for, 1464

Intracellular pathogens

- *Coxiella burnetii*, 916
- *Francisella tularensis*, 924
- *Legionella*, 948

Intracerebral cysts, *Taenia serialis* (coenurosis) causing, 1410

Intracranial calcifications, congenital toxoplasmosis causing, 1355, 1357

Intracranial disease, headache, 176

Intracranial pressure, increased

  management of, in acute bacterial meningitis, 286

  in meningococcal disease, 754

  Naegleria fowleri infection and, 1337

  Taenia solium neurocysticercosis and, 1401

Intragenic recombination, in drug resistance, 1469

Intramedullary tumors, 190

Intramuscular administration
  of hepatitis b immune globulin, 38–39
  of human rabies immune globulin, 39
  of immune globulins, 38–39
  of tetanus immune globulin, 39
  of varicella-zoster immune globulin, 39
Intranuclear inclusions, CMV and, 1441
Intrapartum antibiotic prophylaxis (IAP), for *Streptococcus agalactiae* (Group B *Streptococcus*) prevention, 727, 727*t*, 728*f*
Intrarenal abscess, 346
Intrauterine contraceptive device
  Actinomyces infections associated with, 1020
  pelvic inflammatory disease and, 367
Intrauterine infections
  HSV causing, 1059–1060, 1063–1064
  Ureaplasma urealyticum causing, 1031
Intravascular catheter-related infections, 601–607
  Candida species, 605
  catheter-related factors of, 602, 602*b*
  clinical manifestations and laboratory diagnosis of, 603–604, 603*t*
  coagulase-negative staphylococci causing, 605
  complications of, 605–606
  epidemiology and pathogenesis of, 601–602, 601*b*–602*b*
  Gram-negative bacilli causing, 605
  host factors of, 602–603
  management and outcome of, 604–605, 604*t*
  nontuberculous mycobacteria causing, 605
  prevention of, 606–607, 606*b*

  Staphylococcus aureus and, 605

Intravascular infections, endocarditis-like, 270

Intravenous antibiotic therapy, for extraintestinal infections, 833

Intravitreal injection, for endophthalmitis, 516*t*

Intussusception, 176

Invasive bacterial infections, 29

Invasive viral infections, 30

Involucrum, 480

Iodamoeba butschlii, 1309*f*, 1317, 1572

  treatment of, 979–980
Leptospira biflexa, 977–978
Leptospira interrogans, 977–978
  Weil syndrome from, 978, 979*f*
Leptospira interrogans serovar *icterohaemorrhagiae*, 978
Leptospirosis, *Leptospira* (leptospirosis)
Leuconostoc, 746–747
  antibiotic resistance of, vancomycin, 1472
  biochemical differentiation of, 747*t*
  bloodstream infections from, 746

meningitis and pneumonia and, 747
  penicillin resistance of, 747
  therapy for, 747
Leuconostoc mesenteroides, 746
Leuconostoc paramesenteroides, 746
Leucovorin (folinic acid)
  for *Pneumocystis jirovecii (carinii)* pneumonia, 1268*t*
  for *Toxoplasma gondii* infection, 1360*t*
Leukemia
  acute lymphoblastic, 589–590
  infections in, mucormycosis, 1248
  myelogenous, 1452
  Oka-Merck varicella vaccine for, 1072
Leukemoid reaction, 1452, 1453*b*
  in Kawasaki disease, 114
γ-Leukocidin, *Staphylococcus aureus* and, 693
Leukocyte adhesion deficiency, 634–635
  characteristics of, 629*t*
  clinical illness associated with, patterns of, 630*t*
  infectious complications of, 630*t*
  pathogens associated with, 629*t*
  types 1, 2, and 3, 634–635
Leukocyte esterase, in urinary tract infections, 344
Leukocytes, 1451–1457, 1452*t*
Leukocytosis
  Borrelia infections and, 986
  Leptospira infections causing, 979
Leukomalacia, periventricular, 726–727

Leukopenia
  in Colorado tick fever, 1120
  Ehrlichia and *Anaplasma* infections causing, 921
  HIV infection causing, 673
Leukorrhea, vaginitis and, 362
Levofloxacin, 1524
  dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*
  pharmacokinetics of, 1499*t*–1505*t*
  spectrum of activity of, 1506*t*–1511*t*
  treatment for
    bacterial keratitis, 508
    childhood TB, 802*t*
    eye infections, 1542*t*–1544*t*
    Legionella, 951
    Mycoplasma hominis infection, 1029
    Mycoplasma pneumoniae infection, 1026
Lice, 985
Lichen scrofulosorum, 465
Light chain deficiency, 622–623
Light chains, in immunoglobulin, 617
Limb anomalies, congenital varicella and, 1068
Limb compartment syndromes, after *Neisseria meningitidis* infection, 755
Limb pain, 185–188
  causes of, 186*b*
  diseases involving bone, 187–188
  infectious causes of, 187–188
  in meningococcal septicemia, 753

noninfectious causes of, 188
soft tissue and fascia diseases causing, 188
Limp
in diskitis, 494
in pyogenic arthritis, 487
Lincosamides, 1520
dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*
pharmacokinetics of, 1499*t*–1505*t*
spectrum of activity of, 1506*t*–1511*t*
Linezolid, 1473, 1522
dosage for, 1490*t*–1498*t*, 1527*t*–1531*t*
mechanism of action of, 1473
pharmacokinetics of, 1499*t*–1505*t*
resistance to, 1468*t*
spectrum of activity of, 1506*t*–1511*t*
treatment for
childhood TB, 802*t*
coagulase-negative staphylococci (CoNS), 710
eye infections, 1544*t*
Mycoplasma pneumoniae infection, 1026
osteomyelitis, 483
Staphylococcus aureus, 704
Lipid-rich intravenous infusions, systemic *Malassezia* infections and, 1251
Lipid storage diseases
acute hepatitis and, 413
generalized lymphadenopathy from, 135
Liponyssoides sanguineus (house mouse mite), 961

Lipopeptides
  dosage for, 1527*t*–1530*t*
  pharmacokinetics of, 1499*t*–1505*t*
  spectrum of activity of, 1506*t*–1511*t*
Lipopolysaccharide (LPS), Endotoxin (lipopolysaccharide)
Liposomal amphotericin B, Amphotericin B, liposomal
Listeria
  biologic response modifiers and, 653
  species, 781
Listeria grayi, 781
Listeria innocua, 781
Listeria ivanovii, 781
Listeria monocytogenes, 781–785, 785*b*
  age-specific incidence of, 782*f*
  antimicrobial susceptibility testing for, 1428*t*
  ataxia from, 180
  bacteremia from, 783–784
  bacterial infections from, in neonate, 549
  bloodstream infection, 783
  brain abscess from, 329, 784
  brainstem encephalitis (rhombencephalitis) and, 784
  clinical syndromes of, 783–784
  CNS infections, 784
  conjunctivitis from, 784
  diagnosis of, 784
  endocarditis from, 784
  epidemiology of, 781–782
  febrile gastroenteritis, 784

- food contamination by, 782
- foodborne, 399*t*–405*t*, 782
  - outbreaks, 782
  - prevention, 785*b*
- immunity to, 782–783
- infection in pregnancy, 783
- iron in, 782
- laboratory misidentification of, 781
- localized infection of, 784
- macrophage invasion and spread via, 782, 783*f*
- meningitis from, 285, 783–784, 784*t*
- neonatal infection of, 783
- pathogen description of, 781
- pathogenesis of, 782
- pneumonia from, 238
- prevention of, 785, 785*b*

- virulence factors of, 782

Listeria seeligeri, 781

Listeria welshimeri, 781

Listeriolysin O, antibodies, 782

Liver
- abscess, 434
  - amebic, visceral leishmaniasis causing, 1329

  chronic meningitis in, 292, 293*t*
  damage, HCV infection and, 1138
    evaluation of, 1140
  Echinococcus granulosus in, 1406, 1407*f*
  Echinococcus multilocularis in, 1408, 1409*f*
  granulomas, *Brucella* species (brucellosis) causing, 888
  necrosis, fulminant, adenoviruses causing, 1099
  transplantation
    for adenovirus infections, 1100
    in *Amanita* poisoning, 408
    Echinococcus multilocularis and, 1409
    for hepatitis A virus, 1216
    infection after, 569
    orthotopic, 421
  traumatic injury to, 434
  trematodes in, 1413
Liver rot, 1415
Loa loa (loiasis), 1293*t*, 1388*t*, 1392–1393, 1393*b*, 1572
  clinical manifestations of, 1392
  eosinophilia from, 1456
  epidemiology of, 1392
  laboratory findings and diagnosis of, 1392–1393
  prevention of, 1393
  treatment of, 1393
Localized extraintestinal infection, *Campylobacter* causing, 901
Löeffler pneumonia, *Ascaris lumbricoides* causing, 1375
Lopinavir, 682*t*, 1490*t*–1498*t*
Loracarbef

  pharmacokinetics of, 1499*t*–1505*t*
  structure of, 1512*f*
Louping ill virus, 1131
Louseborne relapsing fevers, 985
  Borrelia species infection and, 986
Low-birthweight infants
  immunization for, 53–55
  viral infections causing, 558
Löwenstein-Jensen agar, 1424*t*
Lower respiratory tract infections (LRTIs)
  adenoviruses causing, 1098*t*, 1099
  Kingella kingae causing, 947
Ludwig angina, 138, 197
Lumbar puncture, 742
  for bacterial infections, in neonate, 553
  contraindications of, 179, 282*t*, 753
    Acanthamoeba infection, 1339–1340
  for encephalitis, 317
  for meningitis, 282
    Neisseria meningitidis, 753
  for sickle hemoglobinopathy, 644–645
  for *Streptococcus agalactiae* (Group B *Streptococcus*) infections, 726
Lumefantrine, 1572
Lumpy jaw, 1020–1021
Lung
  abscess, 247–249
    anaerobic, 248
    clinical manifestations of, 248

  diagnosis of, 248–249, 248*f*–249*f*
  differential diagnosis of, 248
  etiologic agents of, 248
  management of, 249
  mediastinal lymphadenopathy from, 152
  pathogenesis of, 248
  percutaneous drainage for, 249
  prognosis and complications of, 249
aspirate, transport systems and media inoculated routinely in, 1423*t*
biopsy
  for *Pneumocystis jirovecii (carinii)* detection, 1267
  pneumonia diagnosis by, 260
chronic meningitis in, 292
dense focal or multifocal infiltrates, causes of, 253, 253*t*
diffuse interstitial infiltrates
  cancer and, 589, 589*f*
  causes of, 255
Echinococcus granulosus in, 1406, 1407*f*
focal consolidative infiltrates, 260*t*
localized infiltrates, cancer and, 587–589
lymphatic drainage of, 149, 149*f*, 149*t*
micronodular infiltrates, 260*t*
reticulonodular infiltrates of, 255
transplant recipients
  adenovirus infections, 1100
  bilateral, for cystic fibrosis, 650
  infections after, 569

  trematodes in, 1413
  unilateral hyperlucent, 254
Lung disease
  chronic pyogenic, brain abscess and, 331
  persistent or recurrent pneumonia and, 255
Lutzomyia, *Leishmania* transmission of, 1323
Lyme disease, *Borrelia burgdorferi* (Lyme disease)
, Lymph nodes
  aspirates, for *Trypanosoma (Trypanozoon) brucei* infection, 1369
  deep cervical chain of, 137
  enlarged, visceral leishmaniasis causing, 1329
  neck masses not involving, 142–144
  nonspecific hyperplasia and, 130
  normal, 128
  specific groups of, 137
  Sporothrix schenckii complex (sporotrichosis) infection in, 1254
  Toxoplasma gondii infection and, 1354
Lymphadenitis/lymphadenopathy, 158–162, 769
  acquired rubella causing, 1144
  acute bilateral lymphadenopathy, 139–141
  cat-scratch disease causing, 882
  characteristics of, 129, 130*t*
  Corynebacterium species causing, 778*t*–780*t*
  differential diagnosis of, 159–161
    axillary nodes, 160
    epitrochlear nodes, 160
    iliac and femoral nodes, 160–161
    occipital nodes, 160

  popliteal nodes, 161
  preauricular nodes, 160, 160*f*
etiologic agents of, 158–159
filarial, 1389
Francisella tularensis infection causing, 924
generalized, 128–135
  autoinflammatory and autoimmune disorders, 135
  causes of, 134–135
  definition of, 129
  drug-induced hyperplasia related to hypersensitivity, 134
  EBV infection and, 1089–1090
  hemophagocytic lymphohistiocytosis, 135
  histiocytic necrotizing lymphadenitis, 135
  histiocytosis, 135
  Hodgkin and non-Hodgkin lymphoma, 134, 134*b*
  hyperthyroidism, 135
  infectious causes of, 130–134, 130*t*, 131*b*, 132*t*–133*t*
  inherited immunodeficiency syndromes, 134
  lipid storage diseases, 135
  lymphoproliferative disorders, 134, 134*b*
  metastatic neoplasms, 134
  multicentric Castleman disease, 135
  papular acrodermatitis, 135
  sarcoidosis, 135
Haemophilus ducreyi (chancroid) and, 933
histopathology of, 130
history and clinical findings of, 159, 159*b*, 159*f*, 159*t*
infectious causes of, 138–142

inguinal, 353–357
  clinical manifestations of, 354, 354*t*
  differential diagnosis of, 354, 356*t*
  epidemiology of, 353–354
  etiologic agents of, 353
  with genital ulcers, 353–355
  laboratory diagnosis of, 354–355, 355*t*
  management of, 354–355
  prevention of, 355
  special considerations of, 355
  without genital ulcers, 355
localized, 158–162
  differential diagnosis of, 159–161
    axillary nodes, 160
    epitrochlear nodes, 160
    iliac and femoral nodes, 160–161
    occipital nodes, 160
    popliteal nodes, 161
    preauricular nodes, 160, 160*f*
  etiologic agents of, 158–159
  history and clinical findings of, 159, 159*b*, 159*f*, 159*t*
  management and therapy of, 161–162, 161*b*, 161*f*
  pathogenesis of, 158
management and therapy of, 161–162, 161*b*, 161*f*
massive, inhalation anthrax and, 770–771
mediastinal and hilar, 148–156
musculoskeletal pain with, 184–185
noninfectious causes of, 142

  nontuberculosis *Mycobacterium* species causing
    clinical manifestations of, 808–810, 809*f*
    treatment of, 811
  pathogenesis of, 130, 130*b*, 158
  subacute or chronic unilateral, 141–142
  Treponema pallidum (syphilis) causing, 970
  Trypanosoma cruzi infections and, 1371
Lymphangiomas, 143–144
Lymphangiomatosis, skull, in recurrent meningitis, 296
Lymphangitis, 162–163
  clinical manifestations of, 162, 163*f*
  differential diagnosis of, 162–163
  etiologic agents of, 162, 162*t*
  filarial, 1389–1390
  groups C and G streptococci causing, 737
  nodular, 461–462
  therapy of, 163
Lymphatic channels, peritonitis pathophysiology, 423
Lymphatic drainage, of lungs and pleura, 149, 149*f*, 149*t*
Lymphatic flow, of head and neck, 136–138, 137*f*, 137*t*
Lymphatic system, 128–135
Lymphedema, filarial, 1390
Lymphocutaneous sporotrichosis, 1254
Lymphocutaneous syndrome, 130
Lymphocytes
  abnormal counts of, 1453*b*
  atypical, EBV infection and, 1091
  in CSF, in chronic meningitis, 293

cytolysis, by *Entamoeba histolytica*, 1312

deficiency, pneumonia in, 257

lymphocytosis and, 1453–1454

Lymphocytic choriomeningitis virus (LCMV), 291, 1190, 1192–1193, 1194*f*

aseptic meningitis from, 302

encephalitis from, 311

eosinophilic meningitis from, 340*t*

laboratory testing of, 318*t*–321*t*

in rodents, 538

Lymphocytic interstitial pneumonitis, Lymphoid interstitial pneumonitis (LIP)

Lymphocytosis, 1453–1454

Bordetella pertussis causing, 895

Lymphogranuloma venereum, *Chlamydia trachomatis*

Lymphoid hyperplasia, *AICDA* and *UNG* deficiency and, 622

Lymphoid interstitial pneumonitis (LIP)

clinical differentiation of, 671*t*

HIV infection causing, 672*f*, 677

imaging of, 678*f*

Pneumocystis jirovecii pneumonia *vs*., 670, 671*t*

presumptive diagnosis of, 671

Lymphoid nodules, submucosal, 128

Lymphoid tissue

anatomy and function of, 128, 129*t*

bronchus-associated, 258

developmental changes of, 129, 129*t*

Lymphoma, CNS

  EBV association and, 1442
  HIV infection causing, 672
Lymphopenia, 1454
Lymphoproliferative disorders
  Cryptococcus infections and, 1256
  generalized lymphadenopathy from, 134, 134*b*
Lyssaviruses, 1176–1177

M

M cells, 842–843
MacConkey agar, 1424*t*
MacConkey-sorbitol agar, 1424*t*
Macrolide-class antibiotics, 1472–1473, 1517–1519
  dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*
  mechanism of action of, 1472
  for *Mycoplasma pneumoniae* infection, 1027
  pharmacokinetics of, 1499*t*–1505*t*
  resistance to, 1468*t*, 1472–1473
  spectrum of activity of, 1506*t*–1511*t*
  for tickborne infections, 546
Macrophage
  activation, by *Treponema pallidum*, 969
  alveolar, 240
  in *Aspergillus* infections, 1238
  Blastomyces dermatitidis phagocytosis and, 1270
  dysfunction, *Aspergillus* infections of, 1241
  enterovirus infections and, 1206
  in *Histoplasma capsulatum*, 1260

immunopathologic consequences of HIV-1 infection on, 666*b*–667*b*

killing of, by *Shigella*, 843

Legionella multiplying in, 948

Leishmania amastigotes in, 1323

Listeria monocytogenes invasion in, 782, 783*f*

mucormycosis of, 1248

phagocytosis, *Shigella infection* pathogenesis, 842–843

Macrophage activation syndrome (MAS), 102, 108

Macula, *Toxoplasma gondii* in, 1355–1356

Maculae cerulae, 1294, 1294*f*

Macular erythema, 445*f*

Macular exanthems, 445

infectious causes of, 446*b*

noninfectious causes of, 446*b*, 447*t*

Macules, 437*t*

blanching, in Rocky Mountain spotted fever *(Rickettsia rickettsii)*, 953

erythematous, 440

secondary syphilis causing, 970

Maculopapular rashes, 445–447

Madurella grisea, 1287

Madurella mycetomatis, 1287, 1288*f*

Mafenide acetate, for burn wound infections, 530, 531*t*

Magnetic resonance angiography, 335, 337*f*

Magnetic resonance cholangiopancreatography (MRCP), 422

Magnetic resonance imaging (MRI), 276

for acute disseminated encephalomyelitis, 325–326, 326*f* for acute flaccid myelitis, 328*f*

  for acute mastoiditis, 228

  for appendicitis, 430

  for *Aspergillus* infections, 1240*f*

  for diskitis, 494–495

  for encephalitis, 317

  for focal suppurative infections of the nervous system, management, 335

  for Guillain-Barré syndrome, 327*f*

  for musculoskeletal pain, 185, 190*f*

  for myocarditis, 272

  for osteomyelitis, 482

  for pyogenic arthritis, 488

  in recurrent meningitis, 299

  for *Taenia solium* neurocysticercosis, 1401

  for transient synovitis, 496

  for transverse myelitis, 327*f*

  for urinary tract infections, 347

Magnitude of effect, 5

Majocchi granuloma, 1285

Major histocompatibility complex (MHC), antigen presentation with, 44

Malabsorption

  Ascaris lumbricoides infections causing, 1374–1375

  Giardia intestinalis (giardiasis) causing, 1318–1319

  hookworm infections causing, 1376–1377

  Strongyloides fuelleborni causing, 1380

  Strongyloides stercoralis causing, 1380

- viral gastroenteritis and, 385

Malaria, *Plasmodium*

- diagnosis/detection of, 1443–1444
- Kawasaki disease *versus*, 1035
- laboratory testing of, 318*t*–321*t*
- optimal tests for, 1437*t*–1440*t*

Measles, mumps, and rubella (MMR) vaccine, 62–64, 1072, 1147, 1157, 1175

Meat

- inspection, for *Trichinella spiralis* infection prevention, 1387
- *Sarcocystis* infection prevention in, 1352
- *Taenia* infection prevention in, 1399
- *Toxoplasma gondii* infection from, 1353
  - prevention of, 1362*t*–1363*t*
- *Trichinella spiralis* infections from, 1386

Mebendazole

- adverse effects of, 1584
- treatment for
  - *Ascaris lumbricoides* infections, 1375, 1572
  - capillariasis, 1572
  - *Echinococcus granulosus*, 1407
  - *Echinococcus multilocularis*, 1409

    - enterobiasis (pinworm), 1572
    - *Enterobius vermicularis* infections, 1379
    - hookworm infections, 1377, 1572
    - intestinal nematodes, 1570
    - *Mansonella perstans*, 1393
    - toxocariasis, 1572
    - *Trichinella spiralis* infection, 1387
    - trichinellosis, 1572
    - trichuriasis, 1572
    - *Trichuris trichiura* infections, 1378
- *MECA* resistance gene, 694
- Meconium, Gram stain of, 783
- Median, 5
- Mediastinal lymphadenopathy, 148–156
  - bacterial causes of, 152
  - characteristics of, 150
  - clinical manifestations of, 150, 150*t*
  - diagnosis of, 150–151
  - diagnostic approach of, 151*t*, 155–156
  - epidemiology of, 149–150, 150*t*
  - fungal causes of, 152–154
  - *Histoplasma capsulatum* and, 1261*b*, 1265*b*
  - imaging studies of, 150
  - infectious causes of, 151–154, 151*t*
  - noninfectious causes of, 154–155
    - malignancy, 154–155, 155*f*
    - other causes, 155
  - tissue diagnosis and biopsy for, 151

viral causes of, 154

Mediastinitis

coagulase-negative staphylococci (CoNS) causing, 710

in heart transplantation, 569

Histoplasma capsulatum (Histoplasmosis) causing, 1264*t*

Mediastinum

anatomy of, 148

anterior, 148

middle, 148

posterior, 148

widened, inhalational anthrax and, 770–771

Medical devices, *Tsukamurella* infections and, 789

Medical history, of recurrent infections, 614–615

Medical literature, evaluation of, 8–9, 9*b*

Medical study, understanding of, 9

Mediterranean spotted fever (MSF)

agents, vectors, and geographic distribution of, 543*t*

clinical and laboratory manifestations of, 544*t*–545*t*

Mefloquine, 83, 1569

adverse effects of, 1585

contraindication for, 1347–1349

for *P. vivax*, 1572

for *Plasmodium*, 1345*t*–1346*t*, 1347–1349

prophylaxis, 1347–1349, 1348*t*

side effects of, 1347–1349

for uncomplicated malaria, 1572

MEFV genes, 122–123

Megakaryocytes, 1457

Meglumine antimoniate
  for cutaneous leishmaniasis, 1330
  for visceral leishmaniasis, 1332
Melarsoprol
  for *Trypanosoma (Trypanozoon) brucei* infection, 1369*t*, 1568
  for *Trypanosoma brucei rhodesiense*, 1572
Men who have sex with men (MSM), 1102
  *Neisseria gonorrhoe*ae infection and, 760, 766*b*
  syphilis, transmission of, 970
Meningeal syphilis, 970
Meningismus, 332
  Angiostrongylus cantonensis causing, 1384
Meningitis, 740*t*, 742
  Actinomyces causing, 290
  acute bacterial, 278–287
    adjunctive therapy for, 286
    antimicrobial resistance and, 283–284, 284*t*
    choice and mode of antimicrobial therapy for, 284, 285*t*
    clinical presentation of, 280–282
    conditions associated with, 279, 279*t*
    CSF findings in, 282, 283*t*, 284
    differential diagnosis of, 281–282
    empiric antibiotic therapy for, 283
    epidemiology of, 278–279, 278*f*–279*f*
    etiologic agents of, 278–279
    head trauma before, 279
    laboratory findings and diagnosis of, 282–283, 282*t*
    life-threatening complications of, 286

  - management of, 283–285
  - monitoring during therapy for, 284–285
  - mortality rate of, 286–287
  - neurosurgery before, 279
  - pathophysiology of, 279–280, 280*f*–281*f*
  - patterns of illness, 281
  - prevention of, 287
  - prognosis of, 286–287
  - supportive care for, 286
  - therapy duration for, 285
  - unusual organisms causing, 285–286
- arboviruses causing, 302
- arenaviruses causing, 302
- aseptic/viral, 301–305
  - clinical manifestations of, 303
  - complications of, 304–305
  - differential diagnosis of, 303–304
  - etiologic agents and epidemiology of, 301–303
  - laboratory findings and diagnosis of, 304
  - *Leptospira* infections causing, 978
  - major causes of, 301*b*
  - management and empiric and definitive therapy for, 304
  - other etiologies of, 303
  - other viruses in, 302
  - pathogenesis and pathology of, 303
  - prevention of, 305
  - prognosis, and sequelae of, 304–305
  - recurrent, 295*b*

  seasonal incidence of, 302*f*
Bacillus anthracis causing, 771
Bacillus cereus causing, 772
bacterial antigen detection for, 1426
Borrelia burgdorferi causing, 290, 292*t*, 303, 982, 982*b*
Brucella species (brucellosis) causing, 289–290, 292*t*, 887–888, 889*t*
Cellulosimicrobium infections and, 789
cerebrospinal fluid analysis for, 292–293
Chlamydophila pneumoniae causing, 303
chronic, 288–295
Citrobacter causing, 827
coagulase-negative staphylococci (CoNS) causing, 709–710
Coccidioides immitis (coccidioidomycosis) and, 291, 292*t*, 1279–1281
Cronobacter causing, 825
cryptococcal, 1256
  HIV infection causing, 678
Cryptococcus species causing, 290
diagnostic tests for, 294*t*
drug-induced, 298
empiric therapy for, 294–295
Enterobacter causing, 825
Enterococcus causing, 286
enteroviruses causing, 301–302, 1208–1209
epidemiology of, 288
Escherichia coli causing, 285–286, 295
etiology of, 288, 293*t*
evaluation of, 291–294, 292*f*

fungi causing, 291, 294*t*
Gram-negative bacteria causing, 285
group B *Streptococcus* causing, 295
Haemophilus influenzae type b (Hib) causing, *Haemophilus influenzae* type b (Hib)
Haemophilus parainfluenzae causing, 933–934
head trauma and, 525
herpesviruses causing, 302
Histoplasma species causing, 290–291, 292*t*
history of, 291
imaging studies for, 292
infant botulism *versus*, 1003*t*
infectious causes of, 288*t*
Kingella kingae causing, 947
, *Klebsiella* causing, 285–286, 295, 821
late-onset, hospital-associated infection causing, 561
leptospirosis and, 290, 292*t*
Leuconostoc, 747
Listeria monocytogenes causing, 285, 783–784, 784*t*
lymphocytic choriomeningitis virus (LCMV) causing, 302
main features of agent causing, 288–291
management of, 726*t*
Mollaret, Mollaret meningitis
mumps, 305
mumps virus causing, 1159
Mycobacterium tuberculosis, *Mycobacterium tuberculosis*
Mycoplasma hominis causing, 290
Mycoplasma pneumoniae causing, 303, 1024–1025

Neisseria gonorrhoeae causing, 761, 764–765
Neisseria meningitidis causing, 295
in neonate, 551–552, 551*t*
Nocardia species causing, 813–814
noninfectious causes of, 289*b*
nontypable *Haemophilus influenzae* causing, 929
nosocomial, *Acinetobacter* species causing, 852
parameningeal infections, manifest as, 289*b*
paramyxoviruses causing, 302
parasites causing, 291, 294*t*
parechoviruses causing, 301–302
Pasteurella multocida causing, 861
physical examination of, 291–292
posttraumatic, 295–296
predisposing conditions of, 293*t*
Proteus causing, 295
Proteus mirabilis causing, 834
Psychrobacter immobilis causing, 968–969
recurrent, 295–300
  anatomic and physiologic abnormalities predisposing, 613*t*
  aseptic, 295, 295*b*
  clinical manifestations of, 298
  congenital anomalies of, 296*b*
  diagnosis of, 298–299
  drug-induced, 298
  epidemiology of, 295–297
  etiologic agents of, 295
  immunologic defects of, 296–298

    - parameningeal foci of, 296*b*
    - pathogenesis of, 297–298
    - prevention and prophylaxis of, 300
    - trauma and congenital defects of, 297
    - treatment of, 299–300
  - recurrent benign lymphocytic, 303
  - *Salmonella* causing, 279
  - *Serratia marcescens* causing, 836
  - with sickle hemoglobinopathy, management of, 645
  - *Sporothrix schenckii* complex (sporotrichosis) and, 1254
  - *Staphylococcus aureus* causing, 286, 295, 700
  - *Streptococcus agalactiae* (Group B *Streptococcus*) and, 724–725, 726*t*
  - *Streptococcus pneumoniae* causing, 295
  - *Treponema pallidum* causing, 289
  - *Tropheryma whipplei* causing, 290
  - *Ureaplasma urealyticum* infection causing, 303
  - viridans streptococci causing, 734
  - viruses causing, 291, 294*t*
  - West Nile virus (WNV) causing, 302
  - *Yersinia pestis* causing, 849
- Meningococcal vaccines, 67–68, 82
- Meningoencephalitic syndrome, in epidemic typhus *(Rickettsia prowazekii)*, 958
- Meningoencephalitis, 305
  - in aseptic meningitis, 304
  - chronic, enteroviral, 1212
  - eosinophilic, 341
    - *Angiostrongylus* causing, 1384, Eosinophilic meningitis

  - *Mycoplasma hominis* infection and, 1028
  - primary amebic (PAM), 1336
    - incidence of, 1338
  - rotaviruses causing, 1123
  - *Trypanosoma (Trypanozoon) brucei* infection and, 1368
  - *Trypanosoma cruzi* infection causing, 1371
- Mental status
  - altered, 180–181, 180*t*
    - *Taenia solium* neurocysticercosis and, 1401
  - brain abscess and, 332
- Meperidine hydrochloride, for acute pancreatitis, 420
- Mercury, exposure from vaccines, 44
- Merkel cell carcinoma, 1107
- Merkel cell virus, 1105–1107
- Merogony, 1334
- Meropenem, 1515–1516
  - dosage for, 1527*t*–1531*t*
    - impaired renal function, 1490*t*–1498*t*
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*
  - structure of, 1512*f*
  - treatment for
    - *Acinetobacter* species, 852
    - acute bacterial meningitis, 285–286
    - perianal cellulitis in cancer, 591
- Merozoites
  - of *Plasmodium*, 1342*f*, 1343
  - of *Sarcocystis*, 1351*f*

Mesenteric lymphadenitis (adenitis), 157, 174

  Yersinia enterocolitica causing, 847

  Yersinia pseudotuberculosis infections and, 131

Mesenteric lymphadenopathy, EBV infection and, 1089–1090

Metabolic abnormalities, 1458

Metabolic acidosis, in necrotizing enterocolitis, 395

Metabolic disorders

  chronic hepatitis and, 415–416

  genetic, infant botulism *versus*, 1003*t*

Metabolism, of antimicrobial agents, 1484

Metacercariae

  of *Clonorchis* and *Opisthorchis*, 1415

  of *Fasciola hepatica*, 1415

  of *Heterophyes* and *Metagonimus*, 1412–1413

  from intestinal trematodes, 1412

Metacestode, of *Echinococcus granulosus*, 1404, 1406*f*

Metagonimiasis, 1412–1413, 1412*t*

Metagonimus yokogawai (metagonimiasis), 1412

Metal metabolism disorders, acute hepatitis and, 413

Metalloproteinase, *Coccidioides immitis* (coccidioidomycosis) and, 1276

Metastatic neoplasms, generalized lymphadenopathy from, 134

Methenamine, 1526

  dosage for, 1527*t*–1530*t*

Methenamine silver, 1433

Methicillin

  resistance to, 1470–1471

    detection of, 1476

  - resistant *Staphylococcus aureus*, in group childcare, 31
  - spectrum of activity of, 1506*t*–1511*t*

N-Methyl-D-aspartate receptor (NMDAR), 180

Methylbenzethonium, for cutaneous leishmaniasis, 1330

Methylobacteriaceae, 856

Methylobacterium mesophilica, 858

Methylobacterium species, 858

Metrifonate, 1572

Metronidazole, 1473, 1524–1525, 1567
  - adverse effects of, 1585
  - dosage for, 1490*t*–1498*t*, 1527*t*–1531*t*
  - formulations of, 1319–1320
  - mechanism of action of, 1473
  - pharmacokinetics of, 1499*t*–1505*t*
  - resistance to, mechanism of, 1468*t*, 1473
  - spectrum of activity of, 1506*t*–1511*t*
  - treatment for
    - abdominal trauma-related infections, 525
    - balantidiasis *(Balantidium coli)*, 1572
    - *Balantioides coli* infection, 1303–1305
    - *Blastocystis hominis* infection, 1572
    - *Clostridium difficile*, 1007–1008
    - *Dientamoeba fragilis* infection, 1572
    - *Entamoeba histolytica* (amebiasis), 1314
    - *Gardnerella vaginalis*, 788
    - *Giardia intestinalis* (giardiasis), 1319, 1320*t*
    - tetanus, 997*t*
    - *Trichomonas vaginalis* infection, 359–360

Mevalonate kinase deficiency, 126–127
  cardinal clinical features of, 126–127
  course, treatment, and outcome of, 127
  epidemiology and etiology of, 126
Micafungin, 1540
  clinical experience of, 1540
  dosing of, 1490*t*–1498*t*
  pediatric data of, 1540
  pharmacology of, 1540
  toxicities of, 1540
  treatment for, *Aspergillus* infections, 1243
Mice, B-lymphocyte-deficient, 1267
Miconazole
  adverse effects of, 1585
  for superficial infection treatment, 1532*t*, 1533
Microaerophilic organism, 987*t*
Microagglutination assay, for F*rancisella tularensis*, 925
Microbial resistance, 1466–1467
Microbial surface components recognizing adhesive matrix molecules (MSCRAMMs), 693
Microbiologic techniques, for bacterial infections, in neonate, 553
Microcephaly, congenital rubella causing, 1146
Micrococcaceae, coagulase-negative, 711–712
Microconidia, of *Histoplasma capsulatum*, 1259
Microdilution methods, susceptibility testing of, 1474–1475
Microhemagglutination test for *T. pallidum* (MHA-TP), 972
Microimmunofluorescence (MIF) test
  for *Chlamydia trachomatis*, 1446

- for *Chlamydophila (Chlamydia) pneumoniae*, 907
- for *Chlamydophila psittaci*, 915

Microscopic agglutination test, for *Leptospira*, 979

Microscopy
- darkfield, 690
- for *Leptospira* infections diagnosis, 979

Microsphere immunoassay, for flavivirus infections, 1131

Microsporidia, 1334–1336
- clinical manifestations of, 1334–1335
- epidemiology of, 1334
- HIV infection with, 1334
- laboratory findings and diagnosis of, 1335
- pathogens of, 1334
- prevention of, 1335
- treatment of, 1335

Microsporidium, 1335*t*

Microsporum audouinii, tinea capitis from, 1282

Microsporum canis
- tinea capitis from, 1282
- tinea corporis from, 1284–1285

Middle ear
- anatomy of, 225–226, 226*f*
- brain abscess, pathogenesis of, 331
- chronic infections of, 329

Middle-ear disease, ataxia from, 182

Middle-ear effusion, acute otitis media with, 221

Miliary tuberculosis, 795

Military recruits

  anthrax prevention and, 771–772
  Mycoplasma pneumoniae in, 1023
  Neisseria meningitidis in, 751
Milk, raw
  Campylobacter fetus and, 903
  etiologic agents in, 398
Miller Fisher syndrome, *Campylobacter* causing, 901
Miltefosine
  adverse effects of, 1585
  for cutaneous infection, 1572
  for cutaneous leishmaniasis, 1330
  for leishmaniasis, 1568–1569
  for mucosal infection, 1572
  for mucosal leishmaniasis, 1330–1332
  for *Naegleria fowleri* infection, 1338
  for visceral leishmaniasis, 1332, 1572
Mineral oil, contamination of *Listeria monocytogenes*, 782
Minimal bactericidal concentration (MBC), for *Streptococcus agalactiae* (Group B *Streptococcus*), 726
Minimum inhibitory concentration (MIC), 1461, 1463
  of antibacterial agents, 1486
  antifungal, 1487
  broth microdilution assay in, 1428
  , interpretative standards, for antimicrobial agents, 1429*t*
    for *Haemophilus*, 1430*t*
    for *Streptococcus pneumoniae*, 1430*t*
  for *Streptococcus agalactiae* (Group B *Streptococcus*) infections, 726
Minocycline, 1519

- dosage for, 1527*t*–1530*t*
- impregnated ventricular drain, eosinophilic meningitis from, 342
- pharmacokinetics of, 1499*t*–1505*t*
- resistance to, 1474
- spectrum of activity of, 1506*t*–1511*t*

Miracidia, 1293
- in schistosomiasis, 1418

Mites, 542

Mitochondrial dysfunction, 688

Mitochondrial fatty acid oxidation, disorders of, acute hepatitis and, 413

MMR, Measles, mumps, and rubella (MMR) vaccine

Mobiluncus, 1019–1020

Mode, 5

Modified measles, 1172

Moellerella wisconsensis, 831

Molds, 1229, 1247–1248
- ubiquitous filamentous, 1244

Molecular fingerprinting, 1433

Molecular methods, for drug resistance detection, 1475

Mollaret meningitis, 298
- chronic oral acyclovir, prevention of, 300

Molluscipoxvirus, 1049*t*, Molluscum contagiosum

Molluscum bodies, 463–464

Molluscum contagiosum, 195*t*, 353, 356, 462–464, 463*f*, 1049*t*, 1053
- clinical manifestations of, 1053
- diagnosis of, 463–464
- differential diagnosis of, 464

epidemiology of, 1053
in group childcare, 30
laboratory findings and diagnosis of, 1053
prevention of, 1053, 1054*b*
treatment for, 1053
Mondini dysplasia, 296–297, 296*f*
Monkey(s)
bites of, 532
diseases associated with, 538–539
Monkeypox, 538
Monkeypox virus, 1049*t*
Monobactams, 1516
dosing of, for impaired renal function, 1490*t*–1498*t*
pharmacokinetics of, 1499*t*–1505*t*
spectrum of activity of, 1506*t*–1511*t*
structure of, 1512*f*
Monoclonal antibodies, 41–42
in HSV infection, 1062
parasites, laboratory diagnosis of, 1432
virus isolation/identification and, 1435
Monocytes, 87, 1454
activation, in trauma, 523
immunopathologic consequences of HIV-1 infection on, 666*b*–667*b*
Monocytosis, 1454, 1454*b*
Mononuclear phagocytes, 629
Mononucleosis syndromes, generalized lymphadenopathy from, 133

“Monospot” assay, for Epstein-Barr virus, 1441
Moraxella, 863–865
  isolation of, media used for, 1425*t*
Moraxella catarrhalis, 863
  acute otitis media from, 864
  epidemiology of, 864
  infective keratitis from, 507
  otitis media from, 216
  sinusitis from, 232, 232*t*
  treatment for, 864–865
Moraxellaceae, 851
Morbilliform, 445
Morbilliform rash, in Kawasaki disease, 1034*f*
Morbillivirus, 1169
Morganella morganii, 833
  AmpC-type β-lactamase for, 834
  cross-reactions with, *Yersinia enterocolitica*, 847
  neonatal infections from, 834
  treatment of, 834
Morganella species, 833–835
  clinical importance of, 835*b*
  clinical manifestations of, 834
  diagnosis of, 835*b*
  duration of therapy, 835*b*
  epidemiology of, 833–834, 835*b*
  management of, 835*b*
  microbiology of, 833–834, 835*b*
  special considerations and, 835*b*

treatment of, 834
Mosaicism, antimicrobial resistance and, 1469
Motavizumab, for RSV infection prevention, 1165
Mother-to-child transmission
prevention, of HIV infection, 660–664, 661*b*
of viruses, 556–557, 556*t*
Motor neuron disease, enteroviruses causing, 1207–1208
Motor vehicle collision, 526
Mott cells, 1368
Mouse bioassay, for *Clostridium botulinum* toxins, 1003
Moxifloxacin, 1524
for bacterial keratitis, 508
dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*
for endophthalmitis, 515–516
for eye infections, 1542*t*–1543*t*
for *Mycoplasma hominis* infection, 1029
for *Mycoplasma pneumoniae* infection, 1026
pharmacokinetics of, 1499*t*–1505*t*
spectrum of activity of, 1506*t*–1511*t*
for *Stenotrophomonas maltophilia*, 874
Muckle-Wells syndrome (MWS), 127
Mucocutaneous candidiasis, chronic, 1232
Mucocutaneous symptom complexes, 108–115
clinical features and cardinal feature of, 114
in conjunctiva, 112
diagnosis and empiric therapy for, 114
differentiating among causes of, 109*t*–110*t*
distinguishing characteristics of, 111–114

  evolution and resolution of, 113
  exanthem and, 111*t*, 112–113, 113*f*
  extremity changes of, 113
  fever and prodrome and, 111–112
  in lips, 112, 112*f*
  in oropharynx, 112
Mucorales, 1247–1248
  necrotizing soft tissue infection and, 470
Mucormycosis (zygomycosis), 1247–1248
  agents of, 1247–1250
  clinical manifestations of, 1248–1249, 1249*b*–1250*b*
  cutaneous infection of, 1249
  diagnosis of, 1249, 1249*b*–1250*b*
  disseminated infection of, 1249
  epidemiology of, 1248, 1249*b*–1250*b*
  focal cerebral infection, 1249
  gastrointestinal tract infection, 1248
  microbiology of, 1249*b*–1250*b*
  nosocomial, 1248
  prevention of, 1249
  pulmonary infection, 1248
  rhinocerebral infection, 1248
  treatment for, 1249, 1249*b*–1250*b*
Mucosal edema, *Trichuris trichiura* causing, 1377–1378
Mucosal infections, 194–197
  complications of, 197
  manifestations, oral, 196*t*
Mucositis

cancer and, 590

in immunocompromised hosts, 195–197

of rectal mucosa, in cancer, 591

SJS and, 108

Mucous membrane infections, 353–357

Mueller-Hinton (MH) medium, 1427

Multicentric Castleman disease, generalized lymphadenopathy from, 135

Multiceps multiceps, 1410–1411, 1411*b*, 1411*f*

Multicollinearity, 6–7

Multidrug resistance (MDR), 741

Salmonella and, 839

Multifocal motor neuropathy, 40–41

Multilocus enzyme electrophoresis (MEE), for bacterial identification, 691

Multilocus sequence typing (MLST), for bacterial identification, 691–692

Multiple interrelated targets, inhibition of, antimicrobial combinations and, 1465–1466

Multivariable model, 6–7

Mumps virus, 195*t*, 1157–1162, 1161*b*–1162*b*

acute pancreatitis from, 419

antibodies to, 1444

aseptic meningitis from, 304

clinical manifestations of, 1158–1159, 1158*f*–1159*f*

CNS infection from, 1159

complications of, 1159

description of pathogen in, 1157

diagnosis/detection of, 1159–1160, 1443–1444

  - epidemiology of, 1157–1158, 1157*f*–1158*f*
  - immune response of, 1158
  - infective keratitis from, 507
  - optimal tests for, 1437*t*–1440*t*
  - orchitis from, 372, 1158–1159
  - other sites of infection by, 1159
  - parotitis from, 419
  - pathogenesis of, 1158
  - in pregnancy, 1159
  - treatment and prevention of, 1160–1161
  - vaccine for, 1160–1161
    - adverse reactions of, 1160
    - contraindications of, 1160–1161
    - control measures in, 1161
    - recommendations for, 1160, 1161*b*
  - viral parotitis from, 198
- Mupirocin
  - for impetigo, 438
  - for peritonitis prevention, 427
- Murine typhus, 959–960
- Murray Valley encephalitis virus, 1131
- Muscle
  - abscess, 190
  - biopsy, for *Trichinella spiralis* diagnosis, 1387
  - cyst in, *Taenia serialis* (coenurosis) causing, 1410
  - diseases, 188
  - pain, poliovirus causing, 1202
  - strength, 182

tenderness, *Trichinella spiralis* infections and, 1387
tissue, *Sarcocystis* infection in, 1350*f*
tone, 182
weakness, 182
proximal, *Corynebacterium diphtheriae* causing, 775
Muscle enzymes, for *Trichinella spiralis* infection diagnosis, 1387
Musculoskeletal pain
back pain, 188–190, 189*t*
history of, 184
laboratory evaluation and imaging of, 185
limb pain, 185–188
physical examination of, 184–185
Musculoskeletal symptom complexes, 184–192
back pain, 188–190, 189*t*
chest pain, 191–192
history of, 184
laboratory evaluation and imaging of, 185
limb pain, 185–188
physical examination of, 184–185
Mushroom poisoning, 379, 398, 408
Mutant prevention concentration (MPC), 1461
MVK genes, 122–123
Myalgia, in aseptic meningitis, 303
Myasthenia gravis
infant botulism *versus*, 1003*t*
Tensilon test for, 1003
Myasthenic syndrome, hypotonia from, 182*t*–183*t*
Mycelia sterilia, 1246

Mycetoma, 814, 1287
  actinomycotic, 1287
  granules (sclerotia), 1287
Mycobacterial infections, HIV infection causing, 680
Mycobacterium
  antimicrobial susceptibility testing for, 1431
  diskitis from, 493
  diversity of, 790
  isolation of, media used for, 1425*t*
  myositis from, 474
  nontuberculosis, 806–812
    , biologic response modifier and, 653
    clinical manifestations of, 807*t*, 808–810
    disseminated infection from
      clinical manifestations of, 810
      treatment of, 811–812
    epidemiology of, 806
    evaluation for, 655
    granulomatous hepatitis from, 417
    immune reconstitution inflammatory syndrome (IRIS) and, 810
    immunoassays for, 808
    intravascular catheter-related infections from, 605
    laboratory diagnosis of, 807–808
    localized skin, soft tissue, and bone infections from
      clinical manifestations of, 808, 809*f*
      treatment of, 810–811
    lymphadenitis from
      clinical manifestations of, 808–810, 809*f*

    - treatment of, 811
  - mediastinal lymphadenopathy from, 152
  - otitis media from, 810
  - pathogenesis of, 806–807
  - pulmonary infection from
    - clinical manifestations of, 810
    - treatment of, 811
  - subacute or chronic unilateral lymphadenitis from, 141–142, 141*f*
  - treatment of, 810–812

Mycobacterium abscessus
  - clinical manifestations of, 807*t*, 808
  - lung disease from, 811
  - treatment for, 811

Mycobacterium avium complex (MAC)
  - AIDS and, 675–676
  - biologic response modifiers and, 653
  - clinical manifestations of, 808, 809*f*
  - epidemiology of, 806
  - inflammatory enteritis from, 392

Mycobacterium bovis, 790
  - chronic mastoiditis from, 229
  - peritonitis from, 424

Mycobacterium chelonae
  - clinical manifestations of, 807*t*, 808
  - necrotizing soft tissue infection from, 470
  - treatment for, 811

Mycobacterium fortuitum

  - clinical manifestations of, 807*t*, 808
  - treatment for, 811
- *Mycobacterium haemophilum*, clinical manifestations of, 807*t*, 808–809
- *Mycobacterium kansasii*
  - clinical manifestations of, 807*t*, 810
  - treatment for, 811
- *Mycobacterium malmoense*, clinical manifestations of, 807*t*
- *Mycobacterium marinum*
  - clinical manifestations of, 807*t*, 808
  - lymphangitis from, 162
  - in rodents, 538
  - skin infection after trauma, 523
  - treatment for, 810–811
- *Mycobacterium simiae*, clinical manifestations of, 807*t*
- *Mycobacterium tuberculosis*, 34, 74, 769, 790–806
  - abdominal disease from, 798
  - adjunctive measures and monitoring of, 805
  - anterior uveitis from, 509
  - aseptic meningitis from, 303
  - brain abscess from, 329
  - Calmette-Guérin (BCG) vaccine for, 805–806
  - cardiac disease from, 795
  - childhood, 791
  - chronic inflammatory enteritis from, 388
  - chronic mastoiditis from, 229
  - chronic meningitis from, 288–289
    - clinical manifestations of, 288
    - epidemiology of, 288

  - laboratory findings and diagnosis of, 288–289
  - pathogenesis of, 288
- clinical manifestations of, 793–798
  - extrathoracic, 795–798
  - intrathoracic, 793–795
- CNS disease from, 796–797
- complex, 790
- congenital disease from, 798
- cutaneous tuberculosis from, 798
- dactylitis from, 798
- diagnosis of, 799–801
  - interferon γ release assays, 800
  - recommendations for, 800–801
  - tuberculin skin test, 799–800
- disseminated (lymphohematogenous) disease, 795–796
- drug resistance of, 792, 793*f*
  - detection of, 1477
  - isoniazid, 1468*t*, 1472, 1477
  - rifampin, 1473, 1477
  - streptomycin, 1469
  - treatment for, 805
- enteritis from, 798
- eosinophilic meningitis from, 342
- epidemiology of, 791–793
  - childhood infections, 791
  - disease incidence and, 791–792, 792*f*, 792*t*
- epididymitis from, 371
- evaluation and treatment of, 654–655

extrapulmonary tuberculosis and, 804
gastrointestinal disease from, 798
genitourinary disease from, 798
in hematogenous congenital TB, 798
in immunocompromised children, 792–793, 792*t*
  treatment of, 804
immunology and pathogenesis of, 790–791, 791*b*
laboratory testing of, 318*t*–321*t*
lymphadenitis from, 130
lymphatic disease from, 796
mediastinal lymphadenopathy from, 152, 152*f*–153*f*
meningitis from, 795, 797*f*
  clinical manifestations of, 796
  microbiologic confirmation of, 796
microbiologic confirmation and drug susceptibility testing for, 800–801
  conventional approach to, 800
  genetic sequencing in, 801
  methods of, 800–801
  nucleic acid amplification for, 800–801
  specimen collection in, 800
miliary tuberculosis from, 795
mothers with, treatment for, 804–805
  contagious at delivery, 805
  noncontagious at delivery, 805
osteoarticular disease from, 797–798
osteomyelitis from, 485
pericarditis from, 275

peritonitis from, 424, 798
persistent pneumonia from, 250
pleural tuberculosis from, 794–795
pneumonia from, 240, 243
psoas muscle abscess from, 190
pulmonary tuberculosis from
  clinical manifestation of, 793–794
  drug-susceptible, treatment for, 804
  Ghon complex in, 793, 793*f*
  obstructive emphysema in, 793–794, 794*f*
  progressive primary, 794, 795*f*
  reactivation, 794, 795*f*
  segmental lesions in, 793, 794*f*
  supraclavicular adenitis in, 793–794, 794*f*
  symptoms and signs, 794
routes of, 791
scrofula in, 796
skeletal TB and, 798
spinal TB and, 797–798
subacute or chronic unilateral lymphadenitis from, 141*f*, 142
tests of, 799–800
TNF inhibitors and, 652
transmission of, 791
treatment for, 801–805
  antituberculosis agents in, 801–803
  corticosteroid in, 805
  ethambutol in, 802–803
  follow-up during, 805

    - household contact with no evidence of disease and, 805
    - isoniazid in, 801
    - principles of, 803
    - pyrazinamide in, 801–802
    - rifampin in, 801
    - second-line agents in, 803, 803*t*
    - special circumstances in, 804–805
    - window prophylaxis in, 804
  - tuberculoma from, 797
  - vertebral osteomyelitis from, 189–190
- *Mycobacterium ulcerans*
  - clinical manifestations of, 807*t*, 808
  - treatment for, 811
  - virulence factors of, 807
- *Mycoplasma*, 690, 1028–1030, 1028*t*
  - *Bordetella pertussis versus*, 895
  - cell wall in, absence of, 1023
  - chronic fatigue syndrome from, 1038*b*
  - detection/diagnosis of, 1446–1447
    - specimens for, 1434
  - genital
    - diagnosis/detection, 1446–1447
    - optimal tests for, 1437*t*–1440*t*
  - transient synovitis from, 496
- *Mycoplasma amphoriforme*, 1028*t*
- *Mycoplasma buccale*, 1028*t*
- *Mycoplasma faucium*, 1028*t*
- *Mycoplasma fermentans*, 1028*t*, 1029

Mycoplasma genitalium, 1028*t*, 1029, 1446–1447
  associated with nongonococcal urethritis, 1029
  discharge and dysuria syndrome from, 349, 350*t*
  pelvic or scrotal pain syndrome from, 352
Mycoplasma hominis, 1028–1029, 1028*t*
  arthritis from, 491
  in aseptic meningitis, 303
  diagnosis of, 1446–1447
    optimal tests for, 1437*t*–1440*t*
  infection associated with, 1029*t*
Mycoplasma lipophilum, 1028*t*
Mycoplasma orale, 1028*t*
Mycoplasma penetrans, 1028*t*, 1029
Mycoplasma pirum, 1028*t*
Mycoplasma pneumoniae, 450, 768, 914–915, 1023–1027, 1028*t*
  acute bilateral lymphadenopathy lymphadenitis from, 139
  additional tests for, 1025–1026, 1026*f*
  adjunctive therapy for, 1027
  altered mental status and, 180
  antibodies to, testing for, 243
  antimicrobial therapy for, 1026–1027
  arthritis from, 491
  aseptic meningitis from, 303
  bronchiolitis from, 234
  clinical manifestations of, 1023–1025
  cold agglutinins in, 1025, 1459*t*
  cough from, 1024
  culture for, 243, 1025

description of, 1023
diagnosis/detection of, 243, 1446
encephalitis from, 312, 315
epidemic, 1023
epidemiology of, 1023
extrapulmonary disease with, 1024–1025, 1024*t*
extrapulmonary specimens, testing of, 1025
hemolysis and anemia from, 1451
laboratory findings and diagnosis for, 1025–1026
laboratory testing of, 318*t*–321*t*
mediastinal lymphadenopathy from, 151–152
molecular methods for, 1025
optimal tests for, 1437*t*–1440*t*
pathogen-specific identification in, 1025
pathogenesis of, 1023
pharyngitis from, 202
pneumonia from, 131, 239, 242
  in immunocompromised patients, diagnosis of, 259–260
  necrotizing pneumonia, 248
  persistent, 250
respiratory tract disease with, 1023–1024, 1024*f*
respiratory tract epithelial damage from, 254
serologic examination for, 1025
size of, 1023
therapy for, 1026–1027
viral infections with, 1023–1024
Mycoplasma primatum, 1028*t*
Mycoplasma salivarium, 1028*t*

Mycoplasma spermatophilum, 1028*t*

, Mycoplasmataceae, 690, 1030

Mycosel medium, 1431

Mycosis

  clinical manifestations of, 1230, 1230*t*

  opportunistic, 1230, 1230*t*

  primary systemic, 1230, 1230*t*

  superficial or inoculation, 1230, 1230*t*

Mycotoxin syndrome, *Fusarium* and, 1245

MYD88 deficiency, pneumonia in, 258

Myelogenous leukemia, 1452

Myeloid leukemoid reaction, 1452, 1453*b*

Myeloperoxidase (MPO) deficiency, 634

  characteristics of, 629*t*

  clinical illness associated with, patterns of, 630*t*

  infectious complications of, 630*t*

  pathogens associated with, 629*t*

Myocardial infarction

  chest pain with, 192*t*

  differential diagnosis of, myocarditis *vs*., 272

Myocarditis, 271–274, 1100

  bacterial, 271

  clinical manifestations of, 271–272, 273*b*

  complications of, 273

  Corynebacterium diphtheriae causing, 775

  Dallas pathologic criteria for, 271

  diagnosis of, 273*b*

  differential diagnosis of, 272

  enterovirus infections causing, 1211
  epidemiology of, 271, 273*b*
  etiology of, 271
  giant cell, 271
  HIV infection causing, 673
  idiopathic, 272
  influenza and, 1184
  in Kawasaki disease, 1033
  laboratory findings and diagnosis of, 272–273
  lymphocytic, 272
  management of, 273, 273*b*
  mortality of, 273
  Naegleria fowleri infection and, 1337
  noninfectious causes of, 272*b*
  parasites causing, 271
  pathophysiology of, 271
  prevention of, 273–274
  toxin-mediated, 271
  Trichinella spiralis infection causing, 1387
  Trypanosoma cruzi infections causing, 1371
  viral prodrome, 271–272
Myocarditis Treatment Trial, 273
Myocardium, *Trypanosoma cruzi* infections causing, 1371
Myonecrosis
  clostridial, 474
  nonclostridial, synergistic, 474
Myopathy, hypotonia from, 182*t*–183*t*
Myopericarditis, enterovirus infections causing, 1210

Myositis, 188, 473–475
  bacterial, 473–474
  chronic inflammatory, 475
  enterovirus infections causing, 1210
  fungal, 474
  infectious causes of, 473*t*
  influenza and, 1184
  microsporidia associated with, 1334
  nonclostridial, 474
  parasitic, 474–475
  tropical, 476
  viral, 475
Myringitis, bullous, *Mycoplasma pneumoniae* causing, 1023–1024
Myroides odoratus, 856
Myroides species, 857–858

N

Naegleria australiensis, 1336
Naegleria fowleri, 1336–1338, 1338*b*
  Acanthamoeba vs., 1338*t*
  clinical manifestations of, 1337
  description of, 1336, 1336*f*–1337*f*
  diagnosis of, 1337
  epidemiology of, 1336–1337
  laboratory testing of, 318*t*–321*t*, 1337
  life cycle of, 1336*f*
  prevention of, 1338
  primary amebic meningoencephalitis from, 312, 315, 322, 1336

- treatment for, 1338
- trophozoites of, 1336, 1337*f*

Naegleria italica, 1336

Nafcillin, 1514
- for dacryocystitis, 519
- dosage for, 1490*t*–1498*t*, 1527*t*–1531*t*
- for necrotizing fasciitis, 525
- pharmacokinetics of, 1499*t*–1505*t*
- spectrum of activity of, 1506*t*–1511*t*

Naftifine, for superficial infection, 1532*t*, 1533

Nagayama spots, in human herpesvirus 6, 1083

Nail, infection of, tinea unguium causing, 1286

Nail fold infections, 441

Nairovirus, 1132, 1133*t*

Nalidixic acid, 1524
- resistance to, *Salmonella*, 840
- spectrum of activity of, 1506*t*–1511*t*

NALP family of receptors, 45

Nasal discharge
- in acute bacterial sinusitis, 231
- causes of, 165*t*
- in common colds, 200
- nontypable *Haemophilus influenzae* causing, 929
- viral nasopharyngitis and, 164
- in viral upper respiratory tract infections, 231

Nasal mucosa, in acute bacterial sinusitis, 231

Nasal swab, transport systems and media inoculated routinely in, 1423*t*

Nasoenteric feeding, for infant botulism, 1004–1005

Nasolacrimal duct obstruction, 503

Nasopharyngeal swab, transport systems and media inoculated routinely in, 1423*t*

Nasopharyngitis, hemorrhagic, fascioliasis causing, 1415

Nasopharynx, bacterial colonization of, in meningitis pathogenesis, 279–280

National Association of State and Public Health Veterinarians (NASPHV), 539–540

National Childhood Vaccine Injury Act, 46

National Health and Nutrition Examination Survey (NHANES), in HCV infections, 1136

National Healthcare Safety Network (NHSN), 560, 592–593

  in central line-associated bloodstream infections, 10

National Institute for Child Health and Human Development Neonatal Research Network (NICHD NRN), 560

National Institute for Health and Care Excellence (NICE), 345

National Nosocomial Infections Surveillance System, on *Enterobacter* spp. infections, 825, 825*t*

Natriuretic peptide, B-type, in endocarditis, 264

Natural killer cells, 89, 89*t*

  deficiency, 642

  non-SCID disease disorders of, 639–643, 640*t*

Natural penicillins, 1514

  spectrum of activity of, 1506*t*–1511*t*

Nausea, acute abdominal pain with, 173

Nebovirus, 1221

Nebulized hypertonic saline, for bronchiolitis, 237

Necator americanus, 1293, 1293*t*, 1373, 1376–1377

  clinical manifestations of, 1374*b*
  infection route of, 1373–1374, Hookworms

Neck
  deep infections, 137–138, 138*f*
  infections, 136–148
  lymphatic flow and fascial spaces of, 136–138, 137*f*, 137*t*
  masses, not involving lymph nodes, 142–144
  stiffness, in acute bacterial meningitis, 281
  superficial cervical nodes of, 137

Necrotizing arteritis, in Kawasaki disease, 1033

Necrotizing enterocolitis (NEC), 388, 394–397
  clinical approach for, 395
  clinical manifestations of, 395, 395*b*
  coagulase-negative staphylococci (CoNS), 709
  complications of, 396, 397*b*
  differential diagnosis of, 395
  epidemiology of, 394, 394*t*
  management of, 395–396
  modified Bell staging for, 396*t*
  operative strategies for, 396

  prognosis of, 396
  secondary peritonitis and, 425

Necrotizing fasciitis, 188, 476–477, 476*t*, 477*f*
  causes of, 525
  diagnosis of, 478, 478*f*

  infection risk and management following, 524*t*
  pathogenesis of, 477–478, 478*f*
  Serratia marcescens causing, 836
  with tense bullae, 450
  treatment of, 478–479, 479*t*
  type 1, 476*t*, 477
  type 2, 476*t*, 477
  type 3, 477
  varicella complication and, 1067*f*
Necrotizing pneumonia, Pneumonia, necrotizing

Necrotizing soft tissue infections (NSTIs), 470–473
  agents causing, in infants and children, 471*b*
  classification of, 470
  clinical presentation of, 472
  diagnosis and management of, 472–473, 472*t*
  pathogenesis of, 471–472
  polymicrobial, 470
Needle(s), infected, sharing of, *Leishmania* transmission, 1324
Needlestick injury, HCV causing, 1137
Negative predictive value (NPV), 2*t*
Negri bodies, 1177
Neisseria, 766–768
  antimicrobial resistance of, trimethoprim-sulfamethoxazole, 1474
  clinical manifestations of, 767–768
  commensal species and, 766
  epidemiology of, 767
  isolation of, media used for, 1425*t*
  microbiology and laboratory diagnosis of, 766
  prevention of, 768
  special considerations of, 768
Neisseria bacilliformis, 767, 767*t*
Neisseria canis, animal bite infection from, 532
Neisseria cinerea, 767, 767*t*
Neisseria elongata, 767, 767*t*
Neisseria flavescens, 767, 767*t*
Neisseria gonorrhoeae, 759–766, 767*t*
  anal discharge, proctitis, proctocolitis, and enteritis syndrome from, 350

antibiotic resistance of, 760–761
antibodies to, 760
antimicrobial susceptibility testing in, 1430
capillary invasion from, 451
in child abuse, 374–376, 374*f*
childhood infections from, 765
Chlamydia trachomatis coinfection, 759
clinical manifestations of, 761–762
collection methods and transport media of, 1422*t*
commensal *Neisseria* species *vs*., 766
conjunctivitis from, 501, 761
control of, 765–766
culture techniques of, 762
diagnosis of, 762–763, 766*b*
    Gram stain evaluation, 762
    nonculture tests, 762–763
discharge and dysuria syndrome from, 349, 350*t*
disseminated gonococcal infection (DGI) and, 762
    treatment of, 764–765
endocarditis from, 761, 764–765
endocervicitis from, 365
epidemiology of, 760, 760*f*
epididymitis from, 371
expedited partner therapy for, 765
immunity to, 759–760
isolation of
    media used for, 1425*t*
    specimens for, 1422

laboratory findings of, 762–763
management of, 763–764, 766*b*
meningitis from, 761, 764–765
microbiology of, 759–760
mucosal infections from, 761–762
  treatment of, 764

  transmission mode of, 1293*t*
Neomycin, treatment for
  ear infections, 1545*t*
  eye infections, 1543*t*
Neonatal conjunctivitis, prevention for, 1541–1543
Neonatal endocarditis, 262

Neonatal hepatitis, 409–410, 416

Neonatal herpes simplex virus infections, characteristics of, 1062*t*

Neonatal infections

- adenoviruses causing, 1098*t*, 1100
- bacterial, 549–555
  - clinical manifestations of, 551–552, 551*t*–552*t*
  - diagnosis of, 550*t*, 552–553, 555*b*
  - epidemiology of, 550–551
  - etiologic agents of, 549–550, 550*t*
  - laboratory findings of, 552–553, 552*t*
  - management of, 553–554, 555*b*
  - pathogenesis of, 551, 551*t*
  - perspective in, 549
  - prevention of, 554–555
  - prognosis of, 554
  - recent advances in, 554
  - sequelae of, 554
- *Citrobacter* causing, 827
- clinical approach to, 547–549
- clinical manifestations of, 547–548, 548*t*
- congenital varicella syndrome and, 1068
- diagnosis of, 548, 549*t*
- *Enterobacter* causing, 825
- enteroviruses causing, 1211–1212
- epidemiology of, 547
- etiologic agents of, 547, 547*t*
- *Klebsiella* causing, 819
- laboratory findings of, 548

  Listeria monocytogenes, 783
  management of, 548–549
  meningitis, *Listeria monocytogenes* causing, 783
  Morganella morganii causing, 834
  nontypable *Haemophilus influenzae* causing, 929
  Pasteurella multocida causing, 861
  Serratia marcescens causing, 836
  Strongyloides fuelleborni infections causing, 1374*t*, 1379
  Strongyloides stercoralis infections causing, 1374*t*, 1379
  tetanus causing, 997
  Ureaplasma urealyticum causing, 1031
  viral infections, 555–560
    clinical manifestations of, 558–559
      cardiac insufficiency, 558–559
      central nervous system infection, 558
      deafness, 559
      ocular abnormalities, 559
      prematurity and low birth weight, 558
      pulmonary disease, 559
      sepsis syndrome, 558
      spontaneous abortion and stillbirth, 558
      syndrome of congenital infection, 558, 558*t*
    epidemiology of, 556–558
    pathogenesis of, 556
Neonatal intensive care unit, healthcare-associated infections in

Non-nucleoside reverse transcriptase inhibitors (non-NRTIs), 682*t*
    cross-resistance, 683
    drugs included, 682*t*
    hypersensitivity with, 683
Nonabsorbable oral agents, treatment for, *Candida* infections, 1237
Nonalcoholic fatty liver disease (NAFLD), chronic hepatitis and, 415
Nonalcoholic steatohepatitis, 415
Noncardiac thoracic surgery, infection chemoprophylaxis in, 75
Nonclostridial myositis, 474
Nonhuman primates, diseases associated with, 538–539
Noninferiority, 6
Nonspecific antibodies, 1458–1459, 1459*t*
Nonsteroidal anti-inflammatory drugs (NSAIDs)
    for aseptic meningitis, 304
    for fever, 94
Nonsuppurative ossifying periostitis, 198–199
Nonsystematic error, 4
Nontuberculosis *Mycobacterium*, *Mycobacterium*, nontuberculosis
Norepinephrine, for septic shock management, 101

Norfloxacin, 1524
  for eye infection treatment, 1542*t*–1543*t*
Normal counts
  of eosinophils, 1454
  of ESR, 1448
  of ferritin, 1451
  of leukocytes, 1452*t*
  of platelets, 1457
  of procalcitonin, 1450
Normal genitourinary system, recurrent urinary tract infection and, 347–348
, Normal microbiota, 579–580
Norovirus(es), 383, 1221
  antibodies to, 1221
  characteristics of, 1222*t*
  clinical manifestations of, 1223
  epidemiology of, 383–385, 1222
  foodborne disease from, 398, 399*t*–405*t*
  gastroenteritis from, 383, 1221–1222, 1224*b*
    epidemiologic features of, 386*t*
    prevention of, 387
  genogroups of, 383
  in group childcare, 27
  structure of, 1221*f*
  transmission of, 383–384, 1222*f*
  treatment for, 1223, 1224*b*
  vaccines for, 387
North American ginseng *(Panax quinquefolium)*, 1151

Norwalk virus, 1221
Nosocomial exposures, of transplant recipients, 567–568
Nosocomial infections, 10
  from cytomegalovirus
    epidemiology of, 1075
    prevention of, 1080
  Legionella, 949
  Stenotrophomonas maltophilia causing, 873
Nosocomial postnatal infection, 557–558
NTM, *Mycobacterium,* nontuberculosis
Nuchal rigidity, 179
  in aseptic meningitis, 303
  Borrelia infections and, 986
  brainstem encephalitis and, 784
Nuclear imaging, for myocarditis, 272
Nucleic acid-active antibiotics, 1522–1526
Nucleic acid amplification
  for arboviruses, 1445
  for *Chlamydia trachomatis*, 1445
  for CMV, 1441
  for HIV, 1444
  for *Kingella kingae*, 947
  for *Mycobacterium tuberculosis*, 800–801
  for *Neisseria gonorrhoeae* detection, 761–762
  for parvovirus B19, 1445
  for RSV, 1442
  techniques for, 1435–1436
  for virus detection, 1434

Nucleic acid amplification tests (NAATs), 349, 737

  for *Chlamydia trachomatis*, 358, 374, 498, 909

  for diagnosis of EV meningitis, 304

  for *Neisseria gonorrhoeae*, 374

  for resistance detection, 1475

  for *Trichomonas vaginalis*, 357

  for urethritis, 357

Nucleic acid hybridization, for *Neisseria gonorrhoeae* detection, 763

Nucleic acid test, for HIV, 668

Nucleoside/nucleotide analogues, antimicrobial drug resistance, 1551–1564, 1553*t*

Nucleotide reverse transcriptase inhibitors (NtRTIs), 682*t*

Null hypothesis, 6

Number needed to treat (NNT), 3*t*, 5, 8

Nutrition

  for HIV infection, 686

  infection prevention after trauma and, 523

  for pneumonia, 244

Nystatin, for superficial infection treatment, 1532, 1532*t*

O

Obesity, as risk factors, in urinary tract infections, 344

Observational studies, 2

Obstetric procedures, in HCV, 1136

Obturator internus abscess, 697

Occult CNS, abnormalities, in recurrent meningitis, 297

Occupational health, 20

Ochrobactrum species, 858

Ocular abnormalities, in fetus and neonate, viral infections causing, 559, 559*t*

Ocular cysticercosis, 1400*f*, 1401, 1402*t*

Ocular discharge, *Chlamydia trachomatis* and, 910

Ocular disease

- with *Mycoplasma pneumoniae*, 1024*t*
- onchocerciasis and, 1392

Ocular infections

- *Kingella kingae* causing, 947
- *Pseudomonas aeruginosa* causing, 868*t*, 870
- *Serratia marcescens* causing, 836
- *Staphylococcus aureus* causing, 696
- treatment for, 1541, 1542*t*–1543*t*

Ocular larva migrans (OLM)

- diagnosis of, 1383
- *Toxocara* and *Baylisascaris* causing, 1381–1384

Ocular motor nerve palsies, 325

Ocular toxocariasis, 513

Oculogenital infection, *Chlamydia trachomatis* from, 912

Oculoglandular infection, *Francisella tularensis* (tularemia) causing, 924

Oculoglandular syndrome, 130

- of Parinaud, 138

Odds ratio (OR), 3*t*, 4

Odontogenic infections, 193–194

- complications of, 197
- *Prevotella* species causing, 1012

Odynophagia, peritonsillar abscess and, 208

Oerskovia (Cellulosimicrobium) species, 789

Oerskovia xanthineolytica (Cellulosimicrobium funkei), 789

Ofloxacin

  chemoprophylactic use for, *Neisseria meningitidis* infection, 756

  treatment for

    Chlamydia trachomatis infections, 913*t*

    ear infections, 1545*t*

    eye infections, 1542*t*–1544*t*

    Mycoplasma pneumoniae infection, 1026

Ofloxacin otic solution, for chronic mastoiditis, 229–230

Oligella species, 858

Oligella ureolytica, 856

Oligella urethralis, 856

Oligoarthritis, juvenile idiopathic, limb, 186, 187*t*

Ombitasvir-paritaprevir-ritonavir, dasabuvir copackaged with, 1558

Omphalitis, coagulase-negative staphylococci (CoNS) causing, 710

Omsk hemorrhagic fever virus, 1131

Onchocerca volvulus (onchocerciasis), 1293*t*, 1388*t*, 1391–1392, 1391*b*, 1391*f*

  clinical manifestations of, 1392

  conjunctivitis from, 501

  epidemiology of, 1391–1392

  laboratory findings and diagnosis of, 1392

  prevention of, 1392

  transmission of, 501

  treatment of, 1392

Onchocercoma, 1392

Online Mendelian Inheritance in Man (OMIM), 122, 617
Onychomycosis (tinea unguium), 1286
O'nyong-nyong virus, 1126
  arthritis from, 491
Oocysts
  of *Cryptosporidium*, 1306
  of *Cyclospora*, 1321

  of *Sarcocystis*, 1350–1351, 1350*f*–1351*f*
  Toxoplasma gondii and, 1352, 1353*f*
Ookinete, *Plasmodium* and, 1342*f*, 1343
Oophoritis, mumps virus causing, 1159
Ophthalmia neonatorum, 497–500
  Chlamydia trachomatis causing, 498
  diagnosis and management of, 500*b*
  etiologic agents of, 498–500
  herpes simplex virus in, 499
  Neisseria gonorrhoeae causing, 498–499, 499*t*
  other infectious causes of, 499–500
  pathogenesis of, 497–498
  pathogens in, prevalence of, 498*t*
  prophylaxis of, 500
Ophthalmic infections, enteroviruses causing, 1210
Ophthalmitis, posttraumatic, *Bacillus cereus* infections causing, 772
Opisthorchis felineus, 1414
Opisthorchis viverrini, 1414
Opportunistic infections

  prevention of, corticosteroids and, 658
  in solid organ transplant recipients, 571
Opportunistic mycoses, 1230, 1230*t*
Opportunistic pathogens
  Enterobacter as, 825
  Klebsiella as, 819
  Pantoea as, 825
  Pseudomonas aeruginosa as, 866
Opsoclonus-myoclonus-ataxia, 182
Opsonization, 45
Opsonophagocytosis, of serogroup B meningococci, 749
Optic neuritis, 324–325
  cat-scratch disease causing, 885
  etiologies of, 324*t*
  incidence of, 324–325
  risk for, 325
  treatment of, 325
OR (odds ratio), 3*t*, 4
Oral candidiasis, 194
  Candida albicans causing, 194
  pseudomembranous, 194
Oral cavity
  Eikenella corrodens in, 860
  infections of, 193–199
  mucosal infections of, 194–197
  viral infections of, 195*t*
Oral hairy leukoplakia, 1093
Oral infections, HIV infections causing, 679

Oral rehydration therapy (ORT)
  of antimicrobial agent, 1465
  for astrovirus infections, 1225
  for *Shigella* infections, 844
  for *Vibrio cholerae* infection, 876*t*, 877
Orbit, cellulitis, 112, 518
  infectious causes of, 518*b*
Orbital infections, 517–522, 521*f*–522*f*
  differential diagnosis of, 517
  pathogenesis of, 517–518
Orbital septum, 517, 518*f*
Orchitis, 372, 373*t*
  bacterial, 371
  Brucella species (brucellosis) causing, 888
  EBV infection, 1090–1091
  enteroviruses causing, 1210–1211
  mumps virus causing, 1158–1159
Orf virus, 1049*t*
Organ failure, pharmacokinetics of, 1480
Organ perfusion impairment, after *Neisseria meningitidis* infection, 755
Organ systems, consequences of infection and antiretroviral therapy by, 686–689
Organ transplant rejection, eosinophilia from, 1456
Organizational phase, in empyema, 245–246
Oritavancin, 1516
  dosage for, 1527*t*–1530*t*
  pharmacokinetics of, 1499*t*–1505*t*

  spectrum of activity of, 1506*t*–1511*t*

  treatment for, *Staphylococcus aureus*, 703–704

Ornidazole, adverse effects of, 1585

Ornithodoros ticks, 986

Ornithosis, *Chlamydia (Chlamydophila) psittaci*

Orolabial infection, HSV causing, 1057–1058, 1057*f*, 1062, 1063*t*

Oropharyngeal candidiasis (thrush), 1232, 1232*f*

Oropharyngeal infection, *Francisella tularensis* (tularemia) causing, 924

Oroya fever, 968

Orthobunyavirus, 1132, 1133*t*

Orthokeratology, 505

Orthomyxoviridae, 1045*t*

  infections, 1046*t*

Orthopedic devices, device-associated infections in, 610–611

Orthopedic halo-pin device, brain abscess from, 331

Orthopedic surgery, infection chemoprophylaxis in, 76

Orthopoxvirus, 1049*t*

  epidemiology of, 1052

Orthostatic intolerance, chronic fatigue syndrome causing, 1039

Oseltamivir

  dosing of, 1490*t*–1498*t*

  for infants, 1186

  for influenza treatment, 1185

, Oseltamivir phosphate, 1565

Osgood-Schlatter disease, 187

Osler nodes, 264

Osteoarticular infections

  - *Brucella* species (brucellosis) and, 887
  - *Kingella kingae* causing, 946–947
    - abortive skeletal system infections, 946–947
- Osteochondritis
  - congenital syphilis causing, 971, 971*f*
  - puncture wound, of foot, 486
  - *Staphylococcus aureus* causing, 697
- Osteochondritis dissecans, 187
- Osteomyelitis, 187–188, 192*t*, 198–199, 480–487
  - acute hematogenous, 480–483
    - clinical characteristics and differential diagnosis of, 480–481, 481*f*
    - duration of therapy for, 483, 483*t*
    - epidemiology of, 480
    - imaging diagnosis of, 481–482
    - laboratory diagnosis of, 481
    - microbiology of, 480
    - pathogenesis of, 480, 480*f*–481*f*
    - treatment of, 482–483
  - anaerobic bacterial, 485, 486*f*
  - anaerobic cocci causing, 1019
  - anaerobic Gram-negative bacilli causing, 1013–1014
  - *Bacillus cereus* causing, 772
  - bite wound and, 536
  - *Blastomyces dermatitidis* and, 1272, 1273*f*
  - cervical spine, *Pasteurella multocida* causing, 861
  - chronic, 486
  - chronic diffuse sclerosing, *Eikenella corrodens* causing, 860

  chronic recurrent multifocal, 486
  coagulase-negative staphylococci (CoNS) causing, 710
  Coccidioides immitis (coccidioidomycosis) and, 1279
  facial, 485–486
  fungal, 485
  Gardnerella vaginalis causing, 788
  Garré, 198–199
  Haemophilus influenzae type b (Hib) and, 928
  infantile maxillary, 198
  K*ingella kingae* causing, 946
  mandibular, 198
  neonatal, 483–484, 483*f*, 552
  nonhematogenous, 485–486
  pelvic, 484–485
  Pseudomonas aeruginosa causing, 870
  pyogenic arthritis and, 487
  with sickle hemoglobinopathies, 485, 485*b*, 645, 645*f*
  Staphylococcus aureus causing, 696–697

pathogenesis and immunity of, 1152–1153
cellular immunity, 1153
chemokines, 1152–1153
cytokines, 1152–1153
humoral immunity, 1153
innate immune responses, 1152–1153
patterns of occurrence of, 235*f*
pneumonia from, 238–239, 1155
prevention of, 1156
seasonal outbreaks of, 235
special considerations in, 1156
transmission of, 1154
treatment of, 1155
upper respiratory tract disease from, 1155
Paralysis

  bladder, poliovirus causing, 1202
  flaccid, West Nile virus causing, 1130
  poliomyelitis, 1202
  soft palate, *Corynebacterium diphtheriae* causing, 775
  tetanospasmin causing, 996
Paralytic shellfish poisoning, 379, 407
Parameningeal infections, manifest as chronic meningitis, 289*b*
Paramyxoviridae, 1045*t*, 1169
  arthritis from, 491*b*
  infections, 1046*t*
Paramyxoviruses
  aseptic meningitis from, 302
  exanthems from, 446*b*
Paranasal sinuses
  anatomy of, 517
  brain abscess, pathogenesis of, 331
  cancer and, 589–590
  endoscopic surgery for, 234
  eye and, 517, 518*f*
  fractures involving, in recurrent meningitis, 295
  infections, in cancer, 589–590
  normal physiology of, 230
  phaeohyphomycosis and, 1246
  pressure in, 230
  retention of secretions in, 230
  rhinocerebral infection and, 1248
  tumors and, 589–590, Sinusitis
Paraneoplastic syndrome, ataxia and, 182

Paraneoplastic vasculitis, 108
Parapharyngeal abscess, 210–211
  clinical manifestations and differential diagnosis of, 211
  etiologic agents, epidemiology and pathogenesis of, 211
  management, complications and prognosis of, 211
Parapharyngeal space, 210–211
Parapneumonic effusion, 244
  biochemical characteristics of, 245*t*
  clinical and radiographic manifestations of, 246, 246*f*
  etiologic agents of, 245
  laboratory findings and diagnosis of, 246
  management of, 246–247
    antimicrobial therapy for, 247
    surgical intervention for, 247
  in *Mycoplasma pneumoniae* infections, 1024
  as necrotizing pneumonia complication, 249
  pathogenesis and pathologic findings of, 245–246
  prognosis of, 247
Parapoxvirus, 1049*t*
  epidemiology of, 1053

Parasites
  Archeozoa, 1292–1293, 1292*b*, 1292*t*
  classification of, 1291–1293
  evolutionary transition of, 1292
  helminths, Helminths
  laboratory diagnosis of, 1432–1433
  Protozoa, Protozoa
Parasitic Animalia, 1292*b*, 1293
Parasitic infections
  burden, disability-adjusted life years and, 1291
  corticosteroid use, infectious complications of, 658
  drugs for, 1572
  eosinophilia from, 1454–1456
  as neglected tropical diseases, 1291–1292
Parasitology, 1291
Parechoviruses, 1205–1213
  aseptic meningitis from, 301–302
  infections, 1212
  neonatal infections from, 1211–1212
    CNS infection and, 1211
    hepatitis and, 1211, 1212*f*
  serotype of, 1205
Parenteral administration, of antimicrobial agent, 1464–1465
Paresthesia, *Angiostrongylus cantonensis* causing, 1384
Parietal lobe abscesses, clinical manifestations of, 331–332, 332*b*
Parietal pericardium, 275
Parinaud oculoglandular syndrome, 138, 139*b*, 504

Paromomycin, 1521
  adverse effects of, 1585
  spectrum of activity of, 1506*t*–1511*t*
  treatment for
    cutaneous leishmaniasis, 1330
    Dientamoeba fragilis infection, 1572
    Entamoeba histolytica (amebiasis), 1314
    Giardia intestinalis (giardiasis), 1319, 1320*t*
    protozoan infections, 1568
    visceral leishmaniasis, 1332
Paronychia, 437*t*, 441
Paronychial infections, 534–535
Parotid gland
  enlargement of, 197
  masses, 144
Parotitis
  acute, enteroviruses causing, 1208
  differential diagnosis of, 1159
  mumps virus causing, 419
  viral, 198
Paroxysmal lateralizing epileptiform discharges (PLEDs), 1059
Parrot fever, *Chlamydia (Chlamydophila) psittaci*
Parvoviridae, 1045*t*
  arthritis from, 491*b*
  infections, 1046*t*
Parvovirus(es)
  arthritis from, 491
  chronic fatigue syndrome from, 1038*b*

- enteric illnesses caused by, 399*t*–405*t*
- exanthems from, 446*b*

Parvovirus B19, 41, 445, 1115*b*
- acute bilateral lymphadenopathy lymphadenitis from, 139
- antibodies and, 1445
- chronic bone marrow failure from, 1116*f*, 1117–1118
- clinical manifestations of, 1115–1118, 1116*t*
- congenital infections, characteristic manifestations of, 548*t*
- diagnosis/detection of, 1118, 1445
  - polymerase chain reaction for, 1115, 1118
- DNA of, 1115, 1118, 1445
- epidemiology of, 1115
- erythema infectiosum (fifth disease) from, 1115–1116, 1116*b*, 1116*f*–1117*f*, 1116*t*
- in group childcare, 30
- hydrops fetalis from, 1116*t*, 1118
- laboratory testing of, 318*t*–321*t*
- myocarditis from, 271
- optimal tests for, 1437*t*–1440*t*
- papular purpuric gloves and socks syndrome and, 1118
- petechiae from, 452
- polyarthropathy syndrome from, 1116*t*, 1117
- in pregnancy, 1118
- pure red cell aplasia from, 1117–1118
- replication of, 1115
- sickle hemoglobinopathy and, 646
- time course of, schematic, 1116*f*
- transient aplastic crisis from, 1115, 1116*f*, 1116*t*, 1117

  transmission of, 1115
  treatment and prevention of, 1118–1119
  viremia and, 1115, 1118
Passive immunization, 37–43
  of hepatitis A, 38
  for HSCT recipients, 577–578
  immune globulin, 37–38
  immune globulin intravenous, 38*t*, 39–41
  immune globulins prepared from human plasma, 42–43
  immunoglobulin products prepared from animal plasma, 42
  indications of, 37
  intramuscular administration of, 37*t*, 38–39
  intravenous administration of, 41
  monoclonal antibodies, 41–42
  neutropenia associated with cancer, 585
  product shortages of, 43
Passive immunoprophylaxis, 746
Passive surveillance, 1
Passively acquired antibodies, 90*f*, 91, 91*t*
Pasteurella, 859–863
  bite wounds infection from, 532
  classification of, 859
  clinical manifestations of, 860–862, 860*f*–861*f*
  lymphangitis from, 162
  microbiology of, 859–860
  pathophysiology and epidemiology of, 860
  treatment and prevention of, 862
Pasteurella aerogenes, 859, 861

Pasteurella bettyae, 859, 861
Pasteurella caballi, horse bite infection from, 532
Pasteurella canis, 859, 861
Pasteurella dagmatis, 859, 861
Pasteurella gallinarum, 859
Pasteurella haemolytica, 859
Pasteurella multocida, 859, 863*b*
  acute bilateral lymphadenopathy lymphadenitis from, 140
  animal bite infection from, 532
  clinical manifestations of, 861
  preseptal cellulitis from, 519
  skin infection after trauma, 523
  treatment and prevention of, 862
Pasteurella pneumotropica, 859, 861
Pasteurella stomatis, 859, 861
Pasteurellaceae, 932
Pastia lines, 203–204
Pastia sign, 113
Patch (skin lesion), 437*t*
Patellofemoral pain syndrome, 187
Pathogen-associated molecular patterns, 94
Pathogen receptors, 86–87
Pathogenicity island
  Burkholderia cepacia and, 872
  cytotoxin-associated gene, in *Helicobacter pylori* infection, 934
  Enterococcus virulence factors and, 730
Pattern recognition receptor (PRR), 45, 95
Paul-Bunnell heterophil test, 1091

PCR, Polymerase chain reaction (PCR)

Peak plasma concentration, 1479

Pediatric autoimmune neuropsychiatric disorders, streptococcal infections and, 722

Pediatric healthcare epidemiology, 10–25

, Pediculosis, 1294–1296, 1296*b*

- clinical manifestations of, 1294, 1294*f*–1295*f*
- diagnosis of, 1294
- epidemiology of, 1294, 1296*b*
- in group childcare, 31
- microbiology of, 1296*b*
- pathogenesis of, 1294
- prevention of, 1296
- treatment for, 1295–1296, 1295*t*, 1296*b*
  - alternative agents, 1296
  - topical agents, 1296
- virulence of, 1294

Pediculus humanus capitis (head louse) infestation, 1294*f*

- clinical manifestations of, 1294
- diagnosis of, 1294, 1294*f*–1295*f*
- epidemiology of, 1294
- pathogenesis of, 1294
- prevention of, 1296
- treatment for, 1295, 1295*t*

Pediculus humanus corporis, as vector, of *Rickettsia prowazekii*, 958

Pediculus humanus humanus (body louse) infestation, 1294*f*

- clinical manifestations of, 1294, 1294*f*
- epidemiology of, 1294

  pathogenesis of, 1294
  treatment for, 1295, 1295*t*
Pediococcus, 747, 747*t*
  biochemical differentiation of, 747*t*
  vancomycin resistance of, 1472
Pediococcus acidilactici, 746
Pediococcus pentosaceus, 746
Pelvic infections, female, anaerobic cocci causing, 1019
Pelvic inflammatory disease (PID), 175, 175*b*, 352, 367–370
  bacterial vaginosis and, 367
  characteristics of, 369*t*
  Chlamydia trachomatis causing, 367, 909
  complications and sequelae of, 369
  diagnosis of, 367–368, 368*b*
  differential diagnosis of, 368*b*
  epidemiology of, 367
  etiologic agents of, 367
  laboratory findings and diagnosis of, 368–369
  management of, 369, 370*b*, 370*t*
  Neisseria gonorrhoeae causing, 367, 765
  pathogenesis and pathologic findings of, 367, 368*f*
  pelvic pain and, 368
  prevention of, 369–370
  risk factors of, 367
  silent, 367
  urethritis and, 360
Pelvic osteomyelitis, 187–188
Pelvic pain, pelvic inflammatory disease and, 368

Pelvic pain syndrome, 350*t*–351*t*, 352
  management of, 352
  presentation and etiologic agents of, 352
Pemphigus syphiliticus, 971
Penciclovir
  resistance to, 1552*t*
  topical, 1559
Pendred syndrome, 297
Penicillin(s), 740*t*, 1513–1515
  prophylaxis
    for asplenia, 647
    for recurrent meningitis, 300
  resistance to
    Leuconostoc, 747
    meningitis, 283–284
    Neisseria meningitidis, 754
    Staphylococcus aureus, 694
    Staphylococcus epidermidis, 710
    of *Streptococcus pneumoniae*, 1471
    viridans streptococci, 734
  treatment for
    Actinobacillus actinomycetemcomitans, 967–968
    Bartonella bacilliformis, 968
    chronic mastoiditis, 230
    Erysipelothrix rhusiopathiae infections, 786
    GAS pharyngitis, 206
    of groups C and G streptococci, 737
    Pasteurella multocida, 862

    - *Rothia dentocariosa* infections, 787
    - *Streptobacillus moniliformis* (rat-bite fever), 967
    - *Streptococcus agalactiae* (Group B *Streptococcus*) infections, 727–728
- Penicillin-binding proteins (PBPs)
  - β-lactams resistance in, 1470
  - penicillin-binding protein 2, in meningococcal infections, 754
  - for viridans streptococci, 734
- Penicillin G, 1514
  - for anaerobic cocci, 1019
  - dosage for, 1490*t*–1498*t*, 1527*t*–1531*t*
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*
  - for *Streptococcus agalactiae* (Group B *Streptococcus*) prevention, 727–728
  - treatment for
    - eye infections, 1543*t*
    - *Leptospira* infections, 980
    - meningococcal meningitis, 754
    - necrotizing fasciitis, 525
    - tetanus, 997*t*
- Penicillin V
  - dosage for, 1527*t*–1531*t*
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*
- Penicillin VK, dosing of, for impaired renal function, 1490*t*–1498*t*
- Penicillinase-resistant penicillin
  - dosage for, 1527*t*–1530*t*

pharmacokinetics of, 1499*t*–1505*t*
Penicillinase-stable penicillins, 1514
spectrum of activity of, 1506*t*–1511*t*
Penicillium species, 1244–1245
Penile ulcer, *Klebsiella (Calymmatobacterium) granulomatis* and, 823*f*
Pentamidine, treatment for
Babesia (babesiosis), 1300–1302
leishmaniasis, 1568
Pneumocystis jirovecii infections, 1568
T. brucei gambiense, 1572
Trypanosoma brucei infection, 1369, 1369*t*
Pentamidine isethionate
adverse effects of, 1585
for *Pneumocystis jirovecii (carinii)* infections, 1268, 1268*t*
Pentavalent antimony, for cutaneous leishmaniasis, 1330*t*–1332*t*
People, exposed, *Corynebacterium diphtheriae* in, 776
Peptidoglycan, 690, 693
Peptococcus, 1018
Peptostreptococcus, 994*t*, 1018
appendicitis from, 429
peritonsillar abscess from, 208
Peramivir, 1565–1566
dosing of, for impaired renal function, 1490*t*–1498*t*
for influenza, 1185
Percussion, of the abdomen, in acute abdominal pain, 174
Percutaneous aspiration, injection, re-aspiration (PAIR), 1407–1408
Perianal bacterial dermatitis, 437*t*, 438, 438*f*
Perianal cellulitis, cancer and, 591

Perianal infections, *Enterobius vermicularis* causing, 1378

Periapical abscess, 193

Periappendiceal abscess, *Rothia dentocariosa* role in, 787

Pericardial effusion, management of, 276

Pericardial fluid

- examination in pericarditis, 276
- in *Histoplasma capsulatum*, 1261

Pericardial friction rub, 275

- enteroviruses causing, 1210

Pericardiectomy, 276

Pericardiocentesis, 276

Pericarditis, 191, 192*t*, 274–278

- bacterial, 275
- clinical manifestations of, 275, 277*b*
- complications of, 276
- *Corynebacterium* species causing, 778*t*–780*t*
- cytomegalovirus causing, 274
- differential diagnosis of, 275–276
  - myocarditis *vs*., 272
- effusive-constrictive, 275
- enteroviruses causing, 274
- epidemiology of, 275, 277*b*
- etiology of, 274–275
  - noninfectious, 274
- fungal, 275
  - management of, 276
- *Haemophilus influenzae* type b causing, 274
- laboratory findings and diagnosis of, 276, 277*b*

- management of, 276, 277*b*, 277*t*
- mortality of, 276–277
- *Mycobacterium tuberculosis* causing, 275
- pathogenesis of, 275
- prognosis of, 276–277
- purulent, 274
  - causes of, 274*t*
  - *Haemophilus influenzae* type b (Hib) and, 928
- recurrence of, 276
- *Staphylococcus aureus* causing, 274, 700
- tuberculous, 275
- viral, 274

Pericardium, 275
- granulomas in, 275

Pericoronitis, 193

Pericystectomy, for *Echinococcus granulosus*, 1406

Perihepatitis, acute (Fitz-Hugh-Curtis syndrome) and, 765

Perinatal infections, 547
- *Campylobacter fetus* from, 903
- *Chlamydia trachomatis* causing, 912, 913*t*
- HSV causing, 1059–1060, 1063–1064

Perineal abscess, 469

Perinephric abscess, 435
- as complications of urinary tract infection, 346

Periocular cellulitis, 519–520

Periodic fever syndromes, 122–123
- children, physical examination and screening laboratory testing for, 118*b*, Fever, periodic

Periodic fever with aphthous stomatitis, pharyngitis, and adenitis (PFAPA syndrome), 108, 123–125

  epidemiology and cardinal clinical features of, 123–125, 125*t*

  lymphadenopathy from, 142

  treatment and outcome of, 125

Periodontal infections, 193–194

Periodontitis, 193

  early-onset, 193–194

  in immunocompromised hosts, 195–197

Periodontium, 193

Periorbital cellulitis, 112, 517

  bacteremic, 520

Periorbital edema

  Bordetella pertussis causing, 896*f*

  Trichinella spiralis infections causing, 1387

Periostitis, congenital syphilis causing, 971

Periostitis ossificans, 198–199

Peripheral blood mononuclear cells (PBMC), culture, for HHV-6 diagnosis, 1442

Peripherally inserted central catheters (PICCs), in cancer, neutropenia and infections, 579

Periporitis staphylogenes, 469

Perirectal abscesses, 469–470

Peritoneal ascites fluid, transport systems and media inoculated routinely in, 1423*t*

Peritoneal catheters, device-associated infections in, 610

Peritoneal cultures, in necrotizing enterocolitis, 395

Peritoneal dialysis, pharmacokinetics of, 1481

Peritoneal fluid, specimen-specific isolation methods in, 1427

Peritonitis, 423–428
  abdominal pain of, 425
  abdominal trauma and, 525
  associated with peritoneal dialysis catheter, *Staphylococcus epidermidis* causing, 710
  Bacteroides species of, 425
  in burn patients, 530
  cancer and, 591
  catheter-associated, 424–425
    management of, 425–427, 426*t*
  causing *Neisseria gonorrhoeae*, 424
  Cellulosimicrobium infections causing, 789
  clinical presentation of, 425
  complications and prognosis of, 427
  in continuous ambulatory peritoneal dialysis, 423
  , diagnosis of, 425
  epidemiology of, 423
  Escherichia coli causing, 423–424
  etiology of, 423–425, 424*t*
  fecal, 427
  fungal, 424
  with *Haemophilus influenzae*, 424
  hospital-associated infection causing, 561
  infectious, 423
  management of, 425–427
  microsporidia associated with, 1334
  mortality rates for, 427
  Mycobacterium bovis causing, 424

  - *Mycobacterium tuberculosis* causing, 424
  - neonatal idiopathic primary, 423–424
  - with nephrotic syndrome, 423
  - pathophysiology of, 423
  - prevention of, 427–428
  - primary, management of, 425
  - primary bacterial, 423–424, 424*t*
  - *Pseudomonas* species causing, 424
  - relapsing, 427
  - *Rothia dentocariosa* role in, 787
  - secondary bacterial, 423, 424*t*, 425
    - management, 427
  - *Staphylococcus aureus*, 424
  - *Streptococcus pneumoniae*, 423–424
- Peritonsillar abscess, 167–168, 208
  - clinical manifestations and diagnosis of, 208
  - complications and prognosis of, 208
  - epidemiology and pathogenesis of, 208
  - etiologic agents of, 208
  - management of, 208
- Peritonsillar space, 138
- Permeability factors, in *Pseudomonas aeruginosa*, 869
- Permethrin, 83
  - adverse effects of, 1585
  - treatment for
    - lice infestation, 1572
    - pediculosis, 1296
    - scabies (mite infestation), 1297, 1572

Persistent bloodstream infections, management of, 565

Person, place, and time, describing illness by, 2

Pertussis, *Bordetella pertussis* (pertussis)

Pertussis-like illness, adenoviruses causing, 1098*t*, 1099

Pesticides, enteric illnesses caused by, 399*t*–405*t*

Pet(s)

- allergies from, 540
- categories of, 537–538
- exposures to, 537
- infections related to, 537–542
  - guidelines in, 540–541, 541*b*
  - prevention measures for, 540
  - recommendations for, 540–541
- injuries from, 540
- nontraditional, 537–538, 538*t*
  - diseases associated with, 538–539
  - nonhuman primates in, 538–539
  - reportable diseases acquired from, in public settings, 540
- traditional, 537

Pet food, contaminated, infections and, 539

Petechiae

- EBV infection and, 1090
- etiology of, 451–453
- pathogenesis of, 451

Petechial hemorrhages, *Trichinella spiralis* infections causing, 1387

Petechial rashes, in Rocky Mountain spotted fever *(Rickettsia rickettsii)*, 953

Petoniphilus, 1018

Peyer patches, hypertrophy of, 176
Phaeohyphomycosis
  agents of, 1245–1247
  clinical manifestations of, 1246
  diagnosis of, 1246
  epidemiology of, 1246, 1247*b*
  laboratory findings of, 1246
  microbiology of, 1247*b*

  of drugs, 1482
  integration of, 1485–1487
Pharyngeal diphtheria, 204
Pharyngeal erythema, 769
  human herpesvirus 6 causing, 1083
Pharyngeal infections, *Neisseria gonorrhoeae* causing, 761
Pharyngeal syndromes, in sexually transmitted infection syndromes, 351*t*, 352
Pharyngitis, 202–208
  acute, causes of, 203*t*

adenovirus causing, 206
Arcanobacterium haemolyticum causing, 202
bacterial, 202, 203*t*, 204
chlamydial, 203*t*
Chlamydophila pneumoniae causing, 202
clinical manifestations of, 202–204
Corynebacterium diphtheriae causing, 202
diagnosis of, 205–206
due to viruses, 204
EBV, 204, 204*f*
epidemiology of, 202
etiology of, 202
Fusobacterium necrophorum causing, 202
gonococcal, 202
group A *Streptococcus* (GAS) causing, 202–204, 203*b*, 203*f*
  antimicrobial agents for, 206, 206*t*
  chronic carriage and recurrences of, treatment failures, 207
  complications of, 207
  diagnostic considerations for, 206
  dosing intervals and duration of therapy of, 206
  follow-up testing for, 206
  macrolide and lincosamide resistance of, 206–207
  nucleic acid detection for, 205
  rapid antigen detection tests for, 205
  throat culture for, 205
  treatment of, 206–207
groups C and G streptococci and, 736
herpes simplex virus (HSV) causing, 202

  HSV infection and, 1057–1058
  infectious mononucleosis and, 1090
  Mycoplasma pneumoniae causing, 202
  mycoplasmal, 203*t*
  Neisseria gonorrhoeae causing, 202
  noninfectious causes of, 203*t*
  rapid antigen detection tests for, 205
  viral, 202, 203*t*
  Yersinia enterocolitica causing, 202
Pharyngoconjunctival fever, adenoviruses causing, 502, 1098*t*, 1099
Phase variation of surface structures, of *Neisseria meningitidis*, 748
Phenylephrine, for septic shock management, 101
Phenylethyl alcohol agar, 1424*t*
Pheromones, antibiotic resistance in *Enterococcus* and, 731
Phlebitis, suppurative, *Staphylococcus aureus* causing, 700
Phlebotomus, *Leishmania* transmission and, 1324
Phlebovirus, 1132, 1133*t*
Phocanema, 1385
Phospholipase, *Gardnerella vaginalis* producing, 788
Phospholipase A_2, 93–94
Photophobia, in aseptic meningitis, 303
Photorhabdus, 831
Phthirus pubis (crab louse) infestation, 1295*f*
  clinical manifestations of, 1294
  in dermatologic syndromes, of sexually transmitted infection syndromes, 353
  diagnosis of, 1294, 1295*f*
  transmission of, 1294

  treatment for, 1295, 1295*t*

Physical examination, for acute abdominal pain, 173–174

Picaridin, for *Plasmodium* infection prevention, 1349

Picobirnaviridae, 1045*t*

  infections, 1046*t*

Picornaviridae, 1045*t*, 1200–1201

  arthritis from, 491*b*

  biology of, 1200–1201, 1201*b*

  classification of, 1200, 1200*t*

  conjunctivitis from, 502–503

  exanthems from, 446*b*

  infections, 1046*t*

  major physical characteristics of, 1200, 1201*b*

  serotypes of, 1200

Piedra, 1287

Piedraia hortae, 1287

Pig(s)

  Balantioides coli infection in, 1303

  Entamoeba polecki in, 1316

  Fasciolopsis buski infection in, 1412

  Sarcocystis in, 1350–1351

  Taenia solium in, 1397–1398, 1398*f*

  Trichinella spiralis in, 1386

Pigbel, 1010

Pigment stones, 421

Pinna, in mastoiditis, 226–227

Pinta, 969, 977

Pintids, 977

Piperacillin
  dosing of, for impaired renal function, 1490*t*–1498*t*
  for eye infections treatment, 1543*t*
  pharmacokinetics of, 1499*t*–1505*t*
  spectrum of activity of, 1506*t*–1511*t*
Piperacillin-tazobactam
  dosage for, 1527*t*–1531*t*
  spectrum of activity of, 1506*t*–1511*t*
  treatment for
    acute mastoiditis, 228–230
    Klebsiella, 821
Piperazine, 1571
  for *Ascaris lumbricoides* infections, 1375
Piperonal, as head louse repellent, 1296
Piperonyl butoxide
  for pediculosis treatment, 1296
  pyrethrins with
    adverse effects of, 1586
    treatment for, lice infestation, 1572
"Pit and pucker", 299*f*
Pitted keratolysis, 437*t*, 439, 439*f*
Pityriasis versicolor, 1251–1252, 1286
  clinical features of, 1286*b*
  diagnosis of, 1286*b*
  epidemiology of, 1286*b*
  microbiology of, 1286*b*
  treatment of, 1286*b*
Placenta

in congenital rubella, 1143
  syphilis in, transmission of, 971
Plague, *Yersinia* pestis
Plain radiographs
  for appendicitis, 429
  for transient synovitis, 496
Plants, freshwater, *Fasciolopsis buski* infection from, 1412
Plaque (skin lesion), 437*t*
Plaque-reduction neutralization tests, for flavivirus infections, 1131
Plasma cells, hyperplasia of, 1092
Plasmapheresis, loiasis, 1393
Plasmids, antimicrobial resistance, 820, 1469
  Citrobacter, 828
  Enterobacter, 826
Plasmodium falciparum (malaria), 1342
  clinical manifestations of, 1343
  diagnosis of, 1344–1345
  encephalitis from, 312
  epidemiology of, 1343
  life cycle of, 1342–1343, 1342*f*
  mortality of, 1291, 1343–1344
  prophylaxis for, 1347, 1348*t*
  treatment for, 1345–1347, 1345*b*–1346*b*, 1345*t*–1346*t*, 1349*b*, *Plasmodium* species (malaria)
Plasmodium folcipanan (uncomplicated malaria), 1572
Plasmodium malariae, 1342
  antimalarial therapy for, 1569
  life cycle of, 1342–1343, 1342*f*

  treatment for, 1345–1347, 1345*b*–1346*b*, 1345*t*–1346*t*, 1349*b*, *Plasmodium* species (malaria)

, *Plasmodium ovale*, 1342

  antimalarial therapy for, 1569

  life cycle of, 1342–1343, 1342*f*

  treatment for, 1345–1347, 1345*b*–1346*b*, 1345*t*–1346*t*, 1349*b*, *Plasmodium* species (malaria)

Plasmodium species (malaria), 1342–1350

  “algid” malaria, 1344

  cerebral malaria, 1344–1345, 1345*b*

  clinical deterioration of, 1346–1347

  clinical manifestations of, 1343, 1349*b*

  description of pathogen, 1342–1343, 1342*f*

  diagnosis of, 1344–1345, 1349*b*

    blood smear, 1344, 1433

  epidemiology of, 1343, 1349*b*

  hyperparasitemia and, 1344

  laboratory findings of, 1344–1345

    Babesia species (babesiosis), 1301*t*

  life cycle of, 1342–1343, 1342*f*

  mortality of, 1343–1344

  nonimmune people, clinical manifestations in, 1344

  in pregnancy, 1349

  prevention of, 1347–1349, 1348*t*

  prophylaxis for, 1347, 1348*t*

    capsule, 1349

    chemoprophylaxis, 1347

    in pregnancy, 1349

  - protective measures in, 1347
  - severe malaria
    - management of, 1345, 1345*t*–1346*t*, 1346*b*
    - manifestations of, 1345*b*, *Plasmodium falciparum* (malaria)
  - thrombocytopenia from, 1458
  - in travelers, 1347
    - prophylaxis, 1349
  - treatment for, 1345–1347, 1345*b*–1346*b*, 1345*t*–1346*t*, 1349*b*
  - uncomplicated malaria, treatment for, 1345*t*–1346*t*, 1347
- *Plasmodium vivax*, 1342
  - antimalarial therapy for, 1569
  - laboratory findings of, 1344–1345
  - life cycle of, 1342–1343, 1342*f*
  - treatment for, 1345–1347, 1345*b*–1346*b*, 1345*t*–1346*t*, 1349*b*, *Plasmodium* species (malaria)
- Platelet(s), 1457–1458
  - physiology and measurement of, 1457
  - thrombocytosis, 1457–1458
  - transfusion, *Bacillus cereus* infection after, 772, Thrombocytopenia
- Platelet activating factor, necrotizing enterocolitis and, 397
- Platyhelminthes, 1293
  - classification of, 1293, 1293*t*
  - transmission mode of, 1293*t*
- Pleconaril
  - for aseptic meningitis, 304
  - for enteroviral infection treatment, 1213
  - for rhinovirus infection treatment, 1220
- Pleocytosis, in aseptic meningitis, 304

Plesiomonas shigelloides, 832–833, 833*b*
Pleura, lymphatic drainage of, 149, 149*f*, 149*t*
Pleural effusion, 244–247
  Burkholderia cepacia infection causing, 872
  clinical and radiographic manifestations of, 246, 246*f*
  Entamoeba histolytica infection causing, 1313–1314
  laboratory findings and diagnosis of, 246
  management of, 246–247
    antimicrobial therapy for, 247
    surgical intervention for, 247
  in *Mycoplasma pneumoniae* infection, 1026
  noninfectious causes of, 245*t*
  pathogenesis and pathologic findings of, 245–246
  prognosis of, 247
  transudate or exudate, 244, 245*t*
  tuberculous, 246
Pleural fluid
  for pneumonia diagnosis, 260
  specimen of, 246
  transport systems and media inoculated routinely in, 1423*t*
Pleural space, 245
Pleurodynia, 192*t*
  enterovirus infections causing, 1210
Pleuropulmonary amebiasis, 1314
Pleuropulmonary infections
  anaerobic, anaerobic cocci causing, 1018
  Eikenella corrodens causing, 860
Pneumatoceles, 242, 247–248

Pneumatosis cystoides intestinalis, 1010

Pneumococcal conjugate and polysaccharide vaccines, 64

Pneumococcal disease, rates of, 739*f*

Pneumococcal otitis media, 7-valent pneumococcal conjugate vaccine for, 222*t*

Pneumocystis carinii

- nomenclature of, 1266, *Pneumocystis jirovecii (carinii)*

Pneumocystis jirovecii (carinii), 1266–1270, 1269*b*

- in AIDS/HIV infection, 1267*f*
  - prevention for, 1269, 1269*t*
- biologic modifier therapy and, 651–652
- breakthrough infections of, 1269
- bronchoscopy for, 1427
- cancer from, 581
- chemoprophylaxis for, 1269, 1269*t*
- clinical manifestations of, 1266
- culture not yet achieved in, 1266
- description of, 1266
- epidemiology of, 1266
- immunocompromised hosts in, 1266
- infections in hematopoietic stem cell transplant recipients, 573, 576
- laboratory findings and diagnosis of, 1266–1267
  - special considerations in, 1267
  - staining methods in, 1267, 1268*f*
- mediastinal lymphadenopathy from, 149–150, 154
- nomenclature of, 1266
- pneumonia (PCP), 171, 239–240, 1266

    - clinical features of, 1266, 1267*f*
    - diagnosis of, 259–260
    - endemic infantile form of, 1266
    - epidemiology of, 1266
    - laboratory findings/diagnosis of, 1266–1267
    - lymphoid interstitial pneumonitis (LIP) *vs*., 671*t*
    - prevention for, 1269, 1269*t*
    - prevention in HIV for, 1269*t*
    - risk factors of, 1269
    - in solid organ transplant recipients, 571
    - treatment for, 1267–1269, 1268*t*
  - prognosis affected by inflammation of, 1266
  - prophylaxis for, 1568
  - rituximab treatment and, 653
  - specimens tested for, 1267*t*
  - transmission of, 1266
  - treatment of infections for, 1267–1269, 1268*t*
- Pneumolysin, 737
- Pneumonia, 170*t*, 238, 742
  - *Acinetobacter* species causing, 852
  - acute, 238–244
    - epidemiology of, 238
    - etiologic agents of, 238–240, 239*t*
  - acute abdominal pain from, 174
  - adenoviruses causing, 241, 250, 1099
  - in adolescents, 238–240, 251
  - after lung transplantation, 569
  - *Aspergillus* causing, 251, 588

bacterial, 238, 240–241
    clinical manifestations of, 241
    diagnosis of, 242–243
    in immunodeficiency, 257, 257*t*
    pathogenesis and pathology of, 240–241
Blastomyces dermatitidis causing, 240*t*, 251, 1271, 1272*f*
bocavirus causing, 238–239
Bordetella pertussis, *Bordetella pertussis* (pertussis)
bronchiolitis obliterans organizing, 254
cancer and, 589
chemical, 241
chest pain with, 192*t*
chest radiography for, 241–242, 242*f*
in children, 238–240
Chlamydia trachomatis causing, 238, 244
chlamydial conjunctivitis and, 498
Chlamydophila pneumoniae causing, 239, 241, 242*f*
Chlamydophila psittaci causing, 239–240, 240*t*, 250, 914
clinical manifestations of, 241
    bacterial pneumonia, 241
    in infants, children, and adolescents, 241
    in neonates and young infants, 241
    viruses, 241
coagulase-negative staphylococci (CoNS) causing, 710
Coccidioides immitis causing, 239–240, 240*t*, 251
community-acquired, microbial causes of, 239*t*
complications of, 244, 250
consolidative, 260, 260*t*

coronaviruses causing, 238–239
Corynebacterium species causing, 778*t*–780*t*
cough in, 241
Coxiella burnetii causing, 239–241, 240*t*, 250
diagnosis of, 242–243
  of bacteria, 242–243
  of other pathogens, 243
  of viruses, 242
differential diagnosis of, 241
EBV causing, 257–258
epidemiology of, 238
Escherichia coli causing, 238
etiologic agents of, 238–240, 239*t*
  bacterial pathogens, 239
  in infants, children, and adolescents, 238–240
  in neonates and young infants, 238
  other pathogens, 239–240, 240*t*
  viruses, 238–239
features of, 171–172, 171*t*–172*t*
fever in, 241
Francisella tularensis (tularemia) causing, 924
fungal, 251
gonococcal, *Neisseria gonorrhoeae* causing, 499
groups C and G streptococci causing, 736
Haemophilus influenzae causing, 250
Haemophilus influenzae type b (Hib) causing, 239, 928
healthcare-associated, 255, 594
  aspiration, 594

  Serratia marcescens and, 836
herpes simplex virus (HSV) causing, 238
Histoplasma capsulatum causing, 239–240, 240*t*, 251
HIV infections causing, 670, 677–678
  empiric antibiotic therapy for, 677
  imaging of, 677, 677*f*–678*f*
  persistent, 255
hospitalization indications in, 243
human herpesvirus 6 (HHV-6) causing, 257
human metapneumovirus (hMPV) causing, 238–239
human parechoviruses causing, 238–239
imaging for, 241–242
in immunocompromised host, 257–261
  clinical diagnosis and radiographic manifestations of, 258–260, 259*f*, 260*t*
  epidemiology of, 257–258
  etiologic agents of, 257–258, 257*t*
  immunodeficiencies, 258
  management and therapy for, 260–261
  pathogenesis and pathologic findings of, 258
  prevention of, 261
  transplant recipients, 258
in infancy, *Chlamydia trachomatis* causing, 910
in infants, Pneumonia, in neonates and young infants
influenza viruses causing, 238–239
laboratory findings of, 241–242
Legionella causing, 587–588, 949
Legionella pneumophila causing, 239–240, 240*t*

Leuconostoc causing, 747

Listeria monocytogenes causing, 238

lobar, 240–241

Löeffler, *Ascaris lumbricoides* causing, 1375

lymphocytic interstitial, 257–258

mortality of, 244

Mycobacterium tuberculosis causing, *Mycobacterium tuberculosis*

Mycoplasma causing, 238

Mycoplasma pneumoniae causing, *Mycoplasma pneumoniae,* pneumonia from

necrotizing, 247–249

  clinical manifestations of, 248

  community-acquired, *Staphylococcus aureus* and, 698, 700*f*

  , diagnosis of, 248–249

  etiologic agents of, 248

  management of, 249

  pathogenesis of, 248

  prognosis and complications of, 249

Neisseria meningitidis causing, 753

in neonates and young infants, 238

  enteroviruses causing, 1211–1212

nodular, 260, 260*t*

parainfluenza viruses causing, 238–239, 1155

Pasteurella causing, 861

pathogenesis and pathology of, 240–241

  bacterial pneumonia, 240–241

  viral pneumonia, 240

persistent, 250–257, 256*b*

  - defined, 250
  - differential diagnosis of, 250
- persistent or progressive at single site, 250–253
  - approach to diagnosis of, 252–253
  - congenital abnormalities of respiratory tract, 252
  - diagnostic considerations for, 250*t*

- retiform, 455
- types of purpuric lesions and, 451, 452*f*

Purpura fulminans, 453

- with tense bullae, 449–450
- varicella complication and, 1067

Purulent material, in antimicrobial activity, 1464

Pustules, 437*t*, 448

Puumala virus, 1132–1134, 1133*t*–1134*t*

Pyelonephritis

- acute abdominal pain from, 174

  clinical manifestations of, 344
  complications of, 346
  Corynebacterium jeikeium and, 780
  procalcitonin in, 1450
  recurrent, 344
  xanthogranulomatous, 834
Pyochelin, *Pseudomonas aeruginosa* producing, 866, 867*t*
Pyogenic arthritis, Arthritis, pyogenic
Pyomyositis, 188, 475–476, 525
  bacterial, 191
  burn wound infections and, 529
  infection risk and management following, 524*t*
  staphylococcal, 476
  Staphylococcus aureus causing, 697
Pyonephrosis, as complications of urinary tract infection, 346
Pyoverdin, *Pseudomonas aeruginosa* producing, 866, 867*t*
PYR reaction, 730
  groups C and G streptococci and, 736
Pyrantel pamoate
  adverse effects of, 1586
  treatment for
    Ascaris lumbricoides infections, 1375
    enterobiasis (pinworm), 1572
    Enterobius vermicularis infections, 1379
    hookworm, 1572
    hookworm infections, 1377
    nematodes, 1571
    Trichuris trichiura infections, 1378

Pyrazinamide
  for childhood TB, 802*t*
  dosing of, 1490*t*–1498*t*
  for tuberculosis, 801–802
Pyrenochaeta spp., 1287
Pyrethrin, for pediculosis treatment, 1296
Pyrethroid, for tickborne infections, 546
Pyrimethamine
  adverse effects of, 1586
  for *Toxoplasma gondii* infection treatment, 1359, 1360*t*
  for toxoplasmosis CNS disease, 1572
Pyrimidine analogs, for systemic fungal infections, 1535*t*, 1536
Pyrin, 126
Pyrogens, 93
Pyrvinium pamoate, 1572
Pyuria, 344
  sterile, 349

Q

Q fever, *Coxiella burnetii* (Q fever)
QALYs, 8
Quality-adjusted life-years (QALYs), 8
, QuantiFERON-TB Gold in-Tube (QFT-GIT) assay, 808
Quasispecies, HCV, 1136
“Query” fever, *Coxiella burnetii* (Q fever)
Quinacrine
  adverse effects of, 1586
  for *Giardia intestinalis* (giardiasis), 1319, 1320*t*

Quinidine
  intravenous, for *Plasmodium* infections, 1345–1346
  for malarial treatment, 1569
  monitoring of, 1345–1346
Quinidine gluconate, treatment for, severe malaria, 1572
Quinine
  as antimalarial therapy, 1569
  for *Babesia* (babesiosis), 1300, 1572
  for *Plasmodium* infections, 1344–1346, 1345*t*–1346*t*
Quinine dihydrochloride, adverse effects of, 1586
Quinine sulfate, 1572
  adverse effects of, 1586
  treatment for
    P. vivax, 1572
    uncomplicated malaria, 1572
Quinolones, 1473, 1523–1524
  mechanism of action of, 1473
  resistance, mechanisms of, 1468*t*, 1473
  spectrum of activity of, 1506*t*–1511*t*
Quinupristin-dalfopristin
  dosage for, 1490*t*–1498*t*, 1527*t*–1530*t*
  pharmacokinetics of, 1499*t*–1505*t*
  spectrum of activity of, 1506*t*–1511*t*
  treatment for
    Staphylococcus aureus, 704
    Ureaplasma, urealyticum, 1032
Quorum sensing, for *Pseudomonas aeruginosa*, 867

R

Rabbit infectivity test (RIT), 970

Rabbits, *Francisella tularensis* infection in, 924

Rabies, 539–540

  prophylaxis, after animal bites, 535

Rabies vaccine, 82

Rabies virus, 1176–1181, 1180*b*

  bat bites and, 311*f*

  clinical manifestations of, 1177–1178

  coma from, 1178

  description of, 1176–1177, 1177*f*

  encephalitis from, 311, 315

  epidemiology of, 1177, 1178*f*, 1178*t*

  furious form of, 315, 1177–1178

  human-to-human transmission of, 1180

  immune response to, 1178

  laboratory diagnosis of, 1178–1179

  optimal tests for, 1437*t*–1440*t*

  paralytic form of, 315, 1178

  pathogenesis of, 1177

  prevention of, 1179–1180

  transmission of, 1177

  treatment of, 1179

  vaccines for, 1179, 1179*t*

    postexposure prophylaxis of, 1179*t*, 1180

    pre-exposure prophylaxis of, 1179–1180

  virulence and immunity of, 1177

  wildlife enzootics of, 1177, 1178*t*

Raccoon, *Baylisascaris procyonis* in, 341, 1382

Race, as risk factors, in urinary tract infections, 344

Radiculoneuritis, *Borrelia burgdorferi* (Lyme disease) causing, 982–983, 982*b*

Radiography

  for diskitis, 494, 495*f*

  for *Echinococcus granulosus* cyst, 1406, 1407*f*

  for musculoskeletal pain, 187

  for necrotizing enterocolitis, 396

  for osteomyelitis, 481–482

  for pyogenic arthritis, 488

Radionuclide cisternography (RC), for recurrent meningitis, 299

Radionuclide scan

  for epididymitis, 371

  for osteomyelitis, 482

Rahnella, 831

Rahnella aquatilis, 831

Ralstonia, 865

Ralstonia mannitolilytica, 865

Ralstonia pickettii, 865

Ralstonia respiraculi, 865

Raltegravir, 682*t*, 683

  dosing of, for impaired renal function, 1490*t*–1498*t*

Ramsay Hunt syndrome, 223, 324

Random misclassification, 4

Randomized controlled trials (RCT), of vaccine efficacy, 7

Range, 5

Raoultella planticola, 819

Raoultella species, 819–822
  clinical manifestations of, 819–820
  diagnosis and management of, 821*b*–822*b*
  microbiology and epidemiology of, 819
  treatment for, infections of, 821
Rape, *Chlamydia trachomatis* and, 1437*t*–1440*t*
Rapid antigen detection tests (RADTs), 205
  GAS and, 1426
  for *Streptococcus agalactiae* (Group B *Streptococcus*), 726
Rapid diagnostic tests (RDTs), for *Plasmodium* infections, 1344
Rapid plasma reagin tests, 1433
Rash(es)
  acquired rubella and, 1144
  acute bacterial meningitis and, 281
  adenoviral infections and, 113
  Colorado tick fever and, 1120
  congenital syphilis and, 971
  Ehrlichia causing, 920–921
  enteroviruses causing, 1208*t*
  epidemic typhus *(Rickettsia prowazekii)* and, 958
  herpes zoster and, 1068
  HIV infection and, 674
  human herpesvirus 6 causing, 1083, 1083*f*
  Kawasaki disease and, 112–113, 1033
  Leptospira infections and, 978
  in Lyme disease, 981–982
  maculopapular, in acute bacterial meningitis, 281
  petechial, *Neisseria meningitidis* causing, 752, 752*f*

  Rickettsia typhi (murine typhus) causing, 959

  Rocky Mountain spotted fever *(Rickettsia rickettsii)* and, 953, 954*f*

  Streptobacillus moniliformis (rat-bite fever) and, 966

  trimethoprim-sulfamethoxazole causing, 1268, 1268*t*

  varicella and, 1067

  varicella vaccine-related, 1072

Rat-bite fever, *Streptobacillus moniliformis*

Rat flea *(Xenopsylla cheopis)*, 959

Raxibacumab, 41–42

Reagin antibody, 1459*t*

Real-time RT-PCR, for influenza viruses, 1184

Recombinant immunoblot assay (RIBA), for HCV, 1139, 1443

Recombination, intragenic, drug resistance and, 1469

Rectal examination, for acute abdominal pain, 173–174

Rectal swabs

  for gastrointestinal virus detection, 1443

  transport systems and media inoculated routinely in, 1423*t*

Recurrent abdominal pain, 176–178

  approach to diagnosis and management of, 177–178

  differentiating causes of, 176–177

Recurrent fever syndromes, 122

  children, physical examination and screening laboratory testing for, 118*b*

Recurrent infections

  clinical approach to, 614–616

    birth history as, 615

    family history as, 615

    genetic testing as, 617

    - history as, 614
    - medical history as, 614–615
    - physical examination as, 615–616, 616*b*
    - screening laboratory tests as, 616–617, 616*t*
    - social history as, 615
    - specialized testing as, 617
    - systems review as, 615
  - management of, 617
  - predisposing anatomic and physiologic abnormalities, 613*t*
  - sentinel pathogens and, 615*t*
  - underlying conditions and, 613, 614*b*
    - frequencies of, 614*t*
- Recurrent respiratory papillomatosis, HPV causing, 1103
- Red cell turnover, parvovirus B19 in, 1118*b*
- Reduviidae, 1369
- Refugee and internationally adopted children
  - guidelines for evaluation of, 33–36, 33*t*
    - Chagas disease, 35–36
    - enteric infections, 35, 35*t*
    - hepatitis A, 33
    - hepatitis B, 33–34
    - hepatitis C, 34
    - human immunodeficiency virus-1, 34
    - human immunodeficiency virus-2, 34
    - infections in, 36
    - syphilis, 36
    - testing in, 36
    - tuberculosis, 34, 35*f*

  infectious diseases in, 32–37
  numbers and countries of origin of, 32
  preventive measure in, 36–37
    immunizations for, 36–37
Regan-Lowe medium, 1424*t*
Regional lymphadenopathy, 129
Rehydration, intravenous, for viral gastroenteritis, 386
Reiter syndrome, 492–493
  Chlamydia trachomatis causing, 910
  urethritis and, 360
Relative risk, 2–3, 3*t*
Relative risk or risk ratio (RR), 3*t*
Renal abscess, 435
Renal complications, of VZV infection, 1067
Renal damage, risk factor for, 343–344
Renal disease, 647
  end-stage, 647
  HIV infection causing, 673
Renal dysfunction
  antiviral agent dosage for, 1554*t*
  dosage adjustment for acyclovir in, 1553*t*
  Leptospira infections and, 978
  Plasmodium infections and, 1344
Renal infections
  Candida spp. causing, 1233–1234, 1234*f*
  Nocardia species causing, 814
  Pseudomonas aeruginosa causing, 870
Renal transplantation

  adenovirus and, 570
  infection after, 568–569
  varicella-zoster virus and, 571
Reoviridae, 1045*t*, 1119
  infections, 1046*t*
Reptiles, diseases associated with, 538
Research hypothesis, 9
Respiratory arrest, infant botulism causing, 1004
Respiratory bacterial infections, 29
Respiratory distress
  in bronchiolitis, 236
  evidence of, 174
  Plasmodium infections causing, 1344
Respiratory failure, in bronchiolitis, 236
Respiratory infections, enteroviruses causing, 1208
Respiratory mucosa, 230
Respiratory rate
  in abdominal pain, 173
  in bronchiolitis, 236
Respiratory syncytial virus (RSV), 1162–1165
  antibodies to, 1442
  apnea from, 236
  bronchiolitis from, 234
  clinical manifestations of, 1164, 1164*b*
  common cold from, 199
  description of, 1162–1163
  diagnosis/detection of, 1442
  epidemiology of, 235, 1163–1164, 1163*b*, 1163*f*

  healthcare-associated transmission of, 1163
  hospitalization due to, 234–235
  in HSCT recipients, 576
  immune response of, 1164
  infections in cancer, 589
  laboratory diagnosis of, 1164
  laboratory testing of, 318*t*–321*t*
  monoclonal antibodies to, 237, 244
  optimal tests for, 1437*t*–1440*t*
  outbreaks, timing of, 235, 235*f*
  pathogenesis of, 1164
  patterns of occurrence of, 235*f*
  pneumonia from, 238, 244
    prevention of, 244
  prevention of, 1165
  , respiratory tract infection from, 1163–1164
  risk factor of, 235
  spread to lower airway, 236
  transmission of, via outpatient clinic, 29
  treatment of, 1164
Respiratory tract
  bacterial and viral pathogens, 74–75
  colonization in, *Haemophilus influenzae*, 927
  congenital abnormalities of, persistent pneumonia and, 252, 252*f*
  Eikenella corrodens in, 860
  involvement, of influenza viruses, 1183
  involvement of, *Brucella* species (brucellosis) and, 888
  specimen-specific isolation methods in, 1426–1427

Respiratory tract disorders, persistent and recurrent pneumonia with, 253–256

Respiratory tract infections

- in burn patients, 529
- in childcare settings, 28–30
- *Enterobacter* causing, 825
- healthcare-associated, 594–596
  - clinical manifestations and laboratory diagnosis of, 595
  - epidemiology and pathogenesis of, 594–595
  - management and outcome of, 595–596, 596*b*
  - viral, 594–596
- nontypable *Haemophilus influenzae* causing, 929
- P*seudomonas aeruginosa* causing, 866, 868*t*
- viridans streptococci causing, 734

Respiratory tract symptom complexes, 164–172

- cough, 168
- mucopurulent rhinorrhea, 164–166
- stridor, 166–168
- tachypnea, 168–171

Respiratory tract symptoms, *Cryptosporidium* infections and, 1307

Respiratory tract viruses

- acute otitis media from, 216
- chronic fatigue syndrome from, 1038*b*
- diagnosis/detection of, 1442
  - shell vial method, 1435
  - specimens for, 1435
- infections in cancer, 589

Respiratory viral infections, 28–29

Restriction fragment length polymorphism (RFLP)
  for *Taenia multiceps*, 1411
  for *Taenia serialis*, 1411
Reticulate body (RB)
  Chlamydia trachomatis and, 908–909
  Chlamydophila (Chlamydia) pneumoniae and, 906
Reticulocytopenia, parvovirus B19 causing, 1115
Retiform purpura, 455
Retina, ocular larva migrans and, 1383, 1383*f*
Retinal necrosis, acute, HSV infection and, 1059
Retinal neovascularization, congenital rubella causing, 1146
Retinitis, 510–513
  ARN and, 512–513
  bacteria causing, 510
  congenital varicella and, 512
  cytomegalovirus causing, 510*t*, 511–512, 512*f*
  fungi causing, 510
  Histoplasma capsulatum causing, 513
  HSV causing, 510*t*, 512
  Rift Valley fever and, 1134
  Rubella causing, 510*t*, 511, 511*f*
  T*oxocara canis* causing, 510*t*, 513
  Toxoplasma gondii causing, 510–511, 510*t*, 511*f*
  West Nile virus causing, 513
Retinoblastoma, *Toxocara* infection misdiagnosis of, 1383
Retinochoroiditis, herpesvirus, 512–513
Retinopathy, “salt-and-pepper,” in congenital rubella, 511, 511*f*
Retroperitoneal abscess, 433*t*, 435–436, 436*b*

  - clinical manifestations of, 435
  - etiology of, 435
  - management of, 435–436
- Retroperitoneal blood, management of, 523
- Retroperitoneal lymphadenopathy, 156–158
  - diagnostic tests of, 157–158
    - biopsy, 158
    - clinical findings and laboratory tests, 157–158
    - imaging studies, 157
  - epidemiology and differential diagnosis of, 156–157, 156*b*, 157*f*
  - therapy for, 158
- Retropharyngeal abscess, 167–168, 208–210
  - clinical manifestations and differential diagnosis of, 209–210, 210*f*
  - complications and prognosis of, 210
  - epidemiology and pathogenesis of, 208–209
  - etiologic agents of, 208
  - management of, 210
- Retropharyngeal space, 138, 208
- Retroviridae, 1045*t*, 1196, 1196*b*
  - arthritis from, 491*b*
  - infections, 1046*t*
- Retroviruses
  - chronic fatigue syndrome from, 1038*b*
  - exanthems from, 446*b*
- Reverse genetics, of human metapneumovirus, 1168
- Reverse transcriptase enzyme, HIV and, 681
- Reverse transcription PCR (RT-PCR)
  - for enteroviruses, 1443

  - for hepatitis viruses, 1443
  - for human metapneumovirus, 1165
  - for measles, mumps, and rubella, 1443–1444
  - for parainfluenza viruses, 1155
  - for retroviruses, 1196
  - for rubeola virus, 1172
- Reye-like syndrome, *Shigella* infection causing, 844
- Reye syndrome, 94
  - influenza and, 1184
  - varicella complication and, 1067
- Rhabdomyolysis, 188
  - *Bacillus cereus* infections and, 772
  - influenza virus-associated, 475
- Rhabdoviridae, 1045*t*
  - infections, 1046*t*
- Rheumatic fever, 76
- Rheumatoid arthritis, acquired rubella causing, 1147
- Rheumatoid factor, 1459*t*
- Rhinitis
  - congenital syphilis and, 971
  - serosanguineous, erosive, 774
- Rhinocerebral mucormycosis, 1248
- Rhinorrhea
  - mucopurulent, 164–166
    - acute, 164–166, 164*t*
    - allergic rhinitis causing, 166
    - bacterial sinusitis causing, 165–166
    - causes of, 164–166, 164*t*

    - management of, 166
    - streptococcal nasopharyngitis causing, 166
    - viral nasopharyngitis causing, 164
  - *Mycoplasma pneumoniae* causing, 1023–1024
- Rhinoviruses, 1219–1221
  - clinical manifestations of, 1220, 1220*f*
  - common cold from, 199, 1219
  - description of pathogen, 1219–1220
  - diagnosis/detection of, 1220, 1442
  - epidemiology of, 1219–1220
  - laboratory findings of, 1220
  - optimal tests for, 1437*t*–1440*t*
  - pneumonia from, 238–239
  - prevention of, 1221
  - special considerations of, 1220
  - transmission of, 1220
  - treatment for, 1220
- *Rhipicephalus sanguineus* (the brown dog tick), as vector, for *Rickettsia rickettsii*, 952
- Rhizobiaceae, 856
- *Rhizobium radiobacter*, 857
- *Rhizomucor*, 1247–1248
- Rhizopoda, 1292
- *Rhizopus*, 1247–1248
- Rho proteins, 390

  treatment of, 962
Rickettsia philipii, 962–963
Rickettsia prowazekii, 957–959
  as agent of bioterrorism, 957–958
  clinical manifestations of, 958
  description of, 957–958
  epidemic typhus
    clinical manifestations of, 958
    complications of, 958
    diagnosis of, 958–959
    epidemiology of, 958
    treatment of, 959
  epidemiology of, 958
  humans, as reservoir of, 958
  , immune response and, 958
  laboratory findings and diagnosis of, 958–959
  prevention and control of, 959
  relapse (Brill-Zinsser disease), 958
    clinical manifestations of, 958

    - prevention of, 959
  - treatment of, 959
- *Rickettsia raoultii*, 964*t*–965*t*
- *Rickettsia rickettsii*, 453, 964*t*–965*t*
  - cross-reactions with, *Yersinia enterocolitica*, 847
  - description of, 952, 952*f*
  - encephalitis from, 312
  - eosinophilic meningitis from, 340*t*
  - epidemiology of, 952–953, 953*f*
  - rickettsial outer membrane proteins of, 952
  - Rocky Mountain spotted fever, 108–111, 543*t*, 952–957, 957*b*
    - clinical manifestations of, 953–955, 954*t*, 955*f*
    - complications from, 956
    - epidemiology of, 953*f*
    - laboratory findings and diagnosis of, 955, 956*f*
    - treatment of, 955–956
  - strains of, 952
- *Rickettsia sibirica*, 964*t*–965*t*
- *Rickettsia sibirica* subsp. *mongolotimonae*, 964*t*–965*t*
- *Rickettsia slovaca*, 964*t*–965*t*
- *Rickettsia* species
  - 364D-associated spotted fever, agents, vectors, and geographic distribution of, 543*t*
  - transmission of, by ticks, 542
- *Rickettsia tarasevichiae*, 964*t*–965*t*
- *Rickettsia typhi*, 959–960
  - clinical manifestations of, 959
  - description of, 959

  epidemiology of, 959
  laboratory findings and diagnosis of, 959–960
  murine typhus and, 959
  prevention of, 960
  treatment of, 960
Rickettsiaceae, 690
Rickettsialpox *(Rickettsia akari)*, 961–962
Rickettsiosis
  Atlantic Rain forest, 962
  cat flea, 960–961
  spotted fever, 964*t*–965*t*
  travel-associated, 963–966
Rifabutin, 1522
  spectrum of activity of, 1506*t*–1511*t*
Rifampin, 1473, 1522
  as antimicrobial therapy, 1465
  for childhood TB, 802*t*
  dosage for, 1527*t*–1530*t*
    impaired renal function, 1490*t*–1498*t*
  impregnated ventricular drain, eosinophilic meningitis from, 342
  pharmacokinetics of, 1499*t*–1505*t*
  resistance to, 1468*t*, 1473
    detection of, 1477
  spectrum of activity of, 1506*t*–1511*t*
  treatment for
    acute bacterial meningitis, 283–284
    Bordetella pertussis, 896
    Brucella species (brucellosis), 888, 889*t*

    - *Haemophilus influenzae* biogroup *aegyptius*, 932
    - *Legionella* infection, 951
    - *Listeria monocytogenes* infections, 784
    - *Naegleria* infections, 1338
    - *Neisseria meningitidis* infection, 756
    - *Staphylococcus aureus* infection, 705
    - *Streptococcus agalactiae* (Group B *Streptococcus*) infections, 727
  - tuberculosis treatment, 801
- Rifamycins, 1522–1523
  - dosage for, 1527*t*–1530*t*
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*
- Rifapentine, 1522
  - spectrum of activity of, 1506*t*–1511*t*
- Rifaximin, 1522
  - dosage for, 1527*t*–1530*t*
  - pharmacokinetics of, 1499*t*–1505*t*
  - spectrum of activity of, 1506*t*–1511*t*
  - for travelers' diarrhea, 84–85
- Rift Valley fever (RVF)
  - clinical manifestations of, 1134, 1134*t*
  - epidemiology of, 1133, 1133*t*
- Right bundle branch, damage in, *Trypanosoma cruzi* infections and, 1371
- Right middle lobe syndrome, 251
- Rilpivirine, 682*t*
  - dosing of, for impaired renal function, 1490*t*–1498*t*
- Rimantadine

- dosing of, for impaired renal function, 1490*t*–1498*t*
- resistance to, 1552*t*

Rings, in trophozoites, of *Plasmodium*, 1343

Ringworm (tinea corporis), 1284–1285, 1285*b*

Risk

- difference, 5
- excess, 5
- measures, 3*t*
- relative/ratio in statistical analysis, 2–3, 3*t*

Risk ratio (RR), 2–3, 3*t*

Risus sardonicus, 996

Ritonavir, 682*t*, 1490*t*–1498*t*

Rituximab

- for EBV, after transplant, 570
- for HIV infection, 673
- *Pneumocystis jirovecii* and, 653

RNA viruses

- negative-sense, 1048*f*
- positive-sense, 1047*f*, *see also* individual viruses

Rocky Mountain spotted fever (RMSF), 108–111

- agents, vectors, and geographic distribution of, 543*t*
- clinical and laboratory manifestations of, 544*t*–545*t*
- Colorado tick fever *versus*, 1121
- encephalitis and, 312
- neutropenia and, 1453

Rodents

- bites, infection after, 532
- diseases associated with, 538

  eradication of, for prevention, murine typhus (*Rickettsia typhi*), 960
  hantavirus in, 1132
  Leishmania reservoir in, 1323
  Leptospira transmission in, 978
  in transmission, of *R. akari*, 961
Romaña sign, 1371, 1371*f*
Romberg test, 182
Rosai-Dorfman disease, lymphadenopathy from, 142
Rose spots, 840
Roseola, 1081–1088
Roseomonas gilardi, 858
Roseomonas species, 858
Ross River virus, 1126
  epidemic polyarthritis caused by, 491
Rotarix (RV1), 1124
RotaTeq (RV5), 1124
Rotavirus vaccine, 68–69
Rotaviruses, 383, 1122–1125, 1125*b*
  antibodies for, 384
  clinical manifestations of, 1123
  description of, 1122, 1122*f*
  diagnosis/detection of, 1443
    tests for, 1123
  enteric illnesses caused by, 399*t*–405*t*
  epidemiology of, 383–385, 1122–1123, 1123*f*
  gastroenteritis from, 383
    epidemiologic features of, 386*t*

  genome of, 383
  group A, 383, 1122
  in group childcare, 27
  hospitalizations attributed to, 377
  laboratory findings for, 1123
  laboratory testing of, 318*t*–321*t*
  optimal tests for, 1437*t*–1440*t*
  porcine circovirus and, 1124
  prevention of, 1124–1125
  proteins of, 383
  treatment for, 1124
  vaccines for, 382, 1124
    future of, 1125
    impact of, 1124–1125, 1124*f*
    Rotarix (RV1), 1124
    RotaTeq (RV5), 1124
    safety of, 1125
Roth spots, 264
Rothia dentocariosa, 786–787, 790*b*
  clinical manifestations of, 787
  epidemiology of, 787
  microbiology of, 786–787
  treatment of, 787
Rothia mucilaginosa, 711–712
rRNA, 691, 691*f*
16s rRNA
  bacterial identification for, 691, 691*f*
  genes, 691, 691*f*

  - *Nocardia* species, 814
  - nonenteric Gram-negative bacilli and, 856
- Rubella, 38, 195*t*
  - antibodies to, 1444
  - congenital infections, characteristic manifestations of, 548*t*
  - diagnosis/detection of, 1443–1444
    - samples for, 1443–1444
  - optimal tests for, 1437*t*–1440*t*
  - retinitis from, 510*t*, 511, 511*f*
- Rubella virus, 1142–1148, 1148*b*
  - acquired
    - clinical manifestations of, 1144
    - complications of, 1147
    - immune response in, 1143
    - incubation period in, 1144
    - laboratory findings and diagnosis of, 1146
    - pathogenesis of, 1142–1143
    - reinfection in, 1144
  - acute bilateral lymphadenopathy lymphadenitis from, 139
  - arthritis from, 491
  - chronic fatigue syndrome from, 1038*b*
  - clinical manifestations of, 1144–1146
  - congenital
    - clinical manifestations of, 1144–1146, 1145*f*, 1146*t*
    - epidemiology of, 1144*f*
    - immune response in, 1143, 1143*f*
    - laboratory findings and diagnosis of, 1146–1147, 1146*t*
    - pathogenesis of, 1143

  - epidemiology of, 1143–1144, 1144*f*–1145*f*
  - immune response to, 1142–1143
  - laboratory findings and diagnosis of, 1146–1147
  - laboratory testing of, 318*t*–321*t*
  - pathogen of, 1142–1143
  - pathogenesis of, 1142–1143
  - prevention of, 1147–1148
    - immunization in, 1147
    - isolation procedures in, 1148
    - passive immunity in, 1147
    - public health measures in, 1148
  - protein in, 1142
  - RNA genome, 1142
  - treatment for, 1147
  - vaccination for, 1142, 1144*f*
- Rubeola virus, 1169–1176, 1176*b*
  - clinical manifestations of, 1171–1172
    - hemorrhagic measles, 1172
    - modified measles, 1172
    - typical measles, 1171–1172, 1172*f*
  - complications of, 1173
    - acute encephalitis as, 1173
    - in central nervous system, 1173
    - cortical brain atrophy as, 1173, 1174*f*
    - otitis media as, 1173
    - in respiratory tract, 1173
  - contagiousness of, 1170
  - description of pathogen, 1169

  epidemics of, 1170
  epidemiology of, 1170–1171, 1170*f*–1171*f*
  genotyping for, 1172
  immune response of, 1169–1170
  in immunocompromised hosts, 1173
  laboratory findings and diagnosis of, 1172
  mediastinal lymphadenopathy from, 154
  neutralizing antibodies for, 1169–1170
  pathogenesis of, 1169
  prevention of, 1174–1175
    active immunization for, 1174–1175
    isolation procedures for, 1175
    MMR vaccine for, 1175
    MMRV vaccine for, 1175
    , passive protection for, 1175
    public health measures and outbreak control for, 1175
  special considerations of, 1173
  transient anicteric hepatitis and, 1172
  treatment of, 1172–1173
  wild-type, 1169
Rubivirus genus, 1142
Ruptured appendicitis scoring system, 431*t*
Ruptured membranes, labor and, HIV infection in, 662–663

S

Saccular aneurysm, in Kawasaki disease, 1034*f*
Saddle nose, congenital syphilis causing, 972
Saksenaea, 1247–1248

Saliva, rabies virus and, 1177
Salivary gland, masses, 144
Salmonella, 454, 1010
  HIV infections and, 679
  infections from, 539
  isolation of, media used for, 1425*t*
  meningitis from, 279
  nontyphoidal
    in foodborne disease, 398, 399*t*–405*t*
    inflammatory enteritis from, 389, 389*t*
  in reptiles, 538
  traveler's diarrhea from, 380
Salmonella choleraesuis, 839
Salmonella dublin, 838
Salmonella enterica, 837
Salmonella enteritidis
  bloodstream infection from, 839–840
  definitive phage type 104 (DT104), 839
Salmonella Paratyphi A
  antimicrobial resistance of, 839
  clinical features of, 840
Salmonella serotype Tilene, in rodents, 538
Salmonella-Shigella agar, 1424*t*
Salmonella species, 837–842, 842*b*
  antimicrobial resistance of, 839
  asymptomatic infection from, 840
  bloodstream infection from, 839–840
  clinical manifestations of, 839–840

cross-reactions with, *Yersinia enterocolitica*, 847
description of, 837–838
diarrhea from, 839
epidemiology of, 838–839
epididymitis from, 371
excretion of, 840
extraintestinal focal infections from, 840
factors predisposing to, 838, 838*t*
foodborne disease from, 838
gastroenteritis from, 839
genome of, 837–838
genome sequencing of, 837–838
healthcare-associated infections from, 838–839
laboratory findings and diagnostic tests for, 840
mesenteric lymphadenitis from, 157
multidrug resistance (MDF) of, 839
nomenclature for, 837–838, 838*t*
nontyphoidal, 838–839
  epidemiology of, 838–839
  reservoir of, 838
  serotypes of, 838, 839*t*
number ingested for disease, 838–839
pathogenesis of, 837–838
prevention of, 841–842
pyogenic arthritis from, 487
sepsis from, 98
septicemia from, 840
serotypes of, 837

- animal-associated, 838, 839*t*
- treatment of, 841
- typhoid fever and, 840

Salmonella typhi, 839
- antimicrobial resistance of, 839
- enteric fever, clinical features of, 840
- genome of, 837–838
- vaccine for, 841, 841*t*
  - Ty21a, 841
  - Vi conjugate, 841–842

Salmonella typhimurium
- bloodstream infection from, 839–840
- genome of, 837–838

Salpingitis, acute, *Neisseria gonorrhoeae* causing, 765

Samples, in statistical analysis, 5
- size, 5–6

Sandifer syndrome, persistent or recurrent pneumonia and, 254–255

Sanger sequencing, for identification, of fungi, 1229–1230

Sapoviruses, 384, 1221
- characteristics of, 1222*t*
- clinical manifestations of, 1223
- epidemiology of, 383–385, 1223
- gastroenteritis from, 384
  - epidemiologic features of, 386*t*
  - sporadic, 384
- genogroups of, 1221

Saprophytes
- growth of, 1431

- of *Histoplasma capsulatum*, 1259
- skin, 528

Saquinavir, 682*t*, 1490*t*–1498*t*

Sarcina, 690

Sarcocystis hominis, 1350–1351

Sarcocystis species, 1350–1352, 1350*f*
- clinical manifestations of, 1351
- diagnosis of, 1351–1352
- epidemiology of, 1351
- life cycle of, 1350*f*
- pathogen, 1350–1351, 1350*f*–1351*f*
- treatment and prevention of, 1352

Sarcocystis suihomini, 1350–1351

Sarcoidosis
- eosinophilic meningitis from, 342
- generalized lymphadenopathy from, 135
- granulomatous hepatitis and, 418
- lymphadenopathy from, 142
- mediastinal lymphadenopathy from, 155

Sarcoptes scabiei (scabies), 353, 1297–1298, 1298*b*
- clinical manifestations of, 1297, 1297*f*
- crusted scabies, 1297
  - treatment for, 1298
- diagnosis of, 1297, 1297*f*
- epidemiology of, 1297, 1298*b*
- microbiology of, 1298*b*
- Norwegian (crusted), in cancer, 587
- pathogenesis of, 1297

- prevention of, 1298
- treatment for, 1295*t*, 1297–1298, 1298*b*
  - crusted scabies, 1298
  - first-line treatments, 1297–1298
  - second-line treatments, 1297–1298
- virulence of, 1297

SARS-CoV, transmission of, 11

Scabies, 353
- in group childcare, 31
- skin infections, in cancer, 587

Scabs, 448

Scalded skin syndrome, staphylococcal, 693*f*, 701–702

Scalp
- abscess, 470
  - coagulase-negative staphylococci (CoNS) causing, 710
  - *Escherichia coli* causing, 470
  - *Neisseria gonorrhoeae* causing, 761
- erythema of, tinea favosa causing, 1285

Scarlatiniform, 445

Scarlet fever, 203
- rash and, 452

Scars, varicella lesions and, 1068

Scedosporium apiospermum, 1290
- microbiology of, 1290

Scedosporium aurantiacum, 1287

Scedosporium prolificans, 1245–1247

Scheuermann kyphosis, 190

Schistosoma, life cycle of, 1419*f*

Schistosoma haematobium, 1293, 1418
Schistosoma intercalatum, 1418
Schistosoma japonicum, 1418
  eosinophilic meningitis from, 340*t*
Schistosoma mansoni, 1293, 1418
Schistosoma mekongi, 1418
Schistosoma species, 1293*t*
  eosinophilia from, 1454–1456
Schistosomiasis, 1418–1421, 1421*b*
  acute, 1419
  biology of, 1418
  clinical features of, 1419–1420
  diagnosis of, 1420, 1420*f*
  epidemiology of, 1418–1419
  growth and development of, 1419–1420
  hepatosplenic disease and, 1419
  intestinal, 1419
  management of, 1420
  pathogenesis of, 1419
  prevention of, 1420
  special considerations to, 1420
  urogenital tract disease and, 1419
Schizogony, 1334, 1342–1343
  exoerythrocytic, 1342–1343
Schizont, *Plasmodium* and, 1342–1343, 1342*f*
Schizonticide, 1347
School absenteeism, chronic fatigue syndrome causing, 1040
SCID-hu mouse model, 1065

Scleral hemorrhages, *Bordetella pertussis* causing, 896, 896*f*
Sclerosing panencephalitis, subacute, Rubeola virus
Scolices, *Taenia* and, 1397*f*
Scombroid, enteric illnesses caused by, 399*t*–405*t*
Scombroid poisoning, 834
Scoring systems, appendicitis and, 430
Scrotal pain, 352
  epididymitis and, 371
  management of, 352
  presentation and etiologic agents of, 352
Scrub typhus, 963–966
Scrum-pox, 1059
Seadornavirus, 1121
Seafood, raw, in eosinophilic meningitis, 341
Seal finger, 532, 1029
Sealpox virus, 1049*t*
Seasonal influenza, on children, 1183
Seborrheic dermatitis
  HIV infection and, 673
  Malassezia causing, 1252
  tinea capitis and, 1284
Seizures
  acute bacterial meningitis and, 280–281, 286
  brain abscess, complication of, 338
  cysticercosis *(Taenia solium)* and, 1400
  human herpesvirus 6 causing, 1083
  infant botulism and, 1003
  Plasmodium infections and, 1343–1344

  Shigella infections and, 844
  Toxocara canis infection and, 1383
Selective enterococcal agar, 1424*t*
Selective media, 1422
Selenite broth, 1424*t*
Selenium sulfide
  for *Malassezia* infections, 1252
  for tinea capitis, 1284
Sendai virus, 1228
Sennetsu fever, generalized lymphadenopathy and, 131
Sensititre, 1428
Sensitivity, 1, 2*t*
Sensitivity analyses, 8
Sensory ganglia, in HSV infections, 1056
Sepsis, 98–102, 99*t*
  biologic markers of, 100
  Citrobacter causing, 827
  clinical signs of, 100
  definitions of, 98, 99*b*, 100*t*
  etiology of, 98–99
  future considerations of, 102
  laboratory findings of, 100
  late-onset, hospital-associated infection causing, 560–561
  management of, 100–102
    antimicrobial therapy, 100–101, 101*t*
    corticosteroids, 101–102
    intravenous immunoglobulin therapy, 101
    supportive care, 101

morbidity and mortality of, 98
neonatal intensive care unit (NICU) associated, corticosteroids and, 657
Pasteurella causing, 861
, pathophysiology of, 99–100
severe, *Staphylococcus aureus* causing, 702
viral infections causing, 558
Septic shock, 98–102, 99*t*
Burkholderia pseudomallei causing, 872
clinical signs of, 100
definitions of, 98, 99*b*, 100*t*
etiology of, 98–99
future considerations for, 102
laboratory findings of, 100
management of, 100–102
antimicrobial therapy, 100–101, 101*t*
corticosteroids, 101–102
intravenous immunoglobulin therapy, 101
supportive care, 101
pathophysiology of, 99–100
pharmacokinetics of, 1482, 1483*t*
Septic thrombophlebitis, 270
management of, 270
risk factors of, 270
Staphylococcus aureus causing, 700
Septic venous thrombosis
clinical manifestations of, 332–333, 333*t*
differential diagnosis of, 333

intracranial, pathogenesis of, 331
Septicemia
Acinetobacter species causing, 852
Aeromonas infection and, 854
after renal transplantation, 568–569
Bacillus anthracis causing, 771
Bacillus cereus infections and, 772
Burkholderia pseudomallei causing, 872
burns wound and, 527
Campylobacter upsaliensis causing, 904
Clostridium septicum causing, 1009*t*
Edwardsiella tarda causing, 830
Enterococcus faecalis causing, 730
Erysipelothrix rhusiopathiae infections and, 786
fulminant, 646
groups C and G streptococci causing, 737
infant botulism *versus*, 1003*t*
Malassezia and, 1252
neonatal, coagulase-negative staphylococci (CoNS) causing, 709
in neonate, 551–552, 551*t*
postpartum/postabortion, *Gardnerella vaginalis* causing, 788
Pseudomonas aeruginosa in, 868*t*, 869*f*
screening tests, for bacterial infections, in neonate, 552–553
secondary infections in varicella and, 1067
with sickle hemoglobinopathy, management of, 645
viridans streptococci causing, 734
Yersinia pestis causing, 849
Sequestra, 480

Serious bacterial infection (SBI), age-related causes of, in very young infants, 115*t*

Serologic approach, 1434, 1436–1437

Serologic tests

  for *Bartonella* species, 884–885

  for *Blastomyces dermatitidis*, 1273

  for *Bordetella pertussis*, 895

  for *Borrelia burgdorferi*, 984

    pitfalls and problems of, 984

  for *Chlamydia trachomatis*, 912, 1446

  for *Chlamydophila (Chlamydia) pneumoniae*, 907

  for CMV, 1441

  for *Coccidioides immitis* (coccidioidomycosis), 1280

  for *Coxiella burnetii*, 917

  for cytomegalovirus, 1078, 1078*b*

  for *Echinococcus multilocularis*, 1408

  for *Entamoeba histolytica* infection, 1314

  for *Enterobius vermicularis*, 1379

  for enteroviruses, 1213

  for epidemic typhus, 959

  for *Francisella tularensis*, 925

  for HCV infection, 1139

  for hepatitis A virus, 1442

  for hepatitis D virus, 1443

  for hepatitis E virus, 1443

  for HHV-6, 1442

  for HHV-7, 1442

  for HHV-8, 1442

  - for *Leptospira* species (leptospirosis), 979
  - for measles, mumps, and rubella, 1443–1444
  - for murine typhus, 960
  - for *Mycoplasma pneumoniae*, 1025
  - for *Neisseria gonorrhoeae* detection, 763
  - for parvovirus, 1445
  - for persistent pneumonia, 253
  - for *Plasmodium*, 1344
  - for rickettsiae, 1433
  - for RSV, 1442
  - for *Toxocara*, 1381–1382
  - for *Toxoplasma gondii*, 1356
  - for *Treponema pallidum* (syphilis), 972
  - for *Trypanosoma (Trypanozoon) brucei* infection, 1368
  - for *Trypanosoma cruzi* infections, 1372
  - for VZV, 1441
    - congenital, 1445
- Serology, for HSV infections, 1062
- Serpiginous urticarial rash
  - *Strongyloides fuelleborni* infections and, 1380
  - *Strongyloides stercoralis* infections and, 1380
- *Serratia ficaria*, 835
- *Serratia fonticola*, 835
- *Serratia liquefaciens*, 835
- *Serratia marcescens*, 835
  - β-lactamases for, 836
  - epidemiology of, 836
  - meningitis from, 836

  microbiology of, 835–836
  neonatal infections from, 836
  treatment of, 836
  urinary tract infection (UTI) from, 836
Serratia odorifera, 835
Serratia plymuthica, 835
Serratia rubidaea, 835
Serratia species, 835–837
  clinical manifestations of, 836, 837*b*
  community-acquired infections from, 836
  diagnosis of, 837, 837*b*
  epidemiology of, 836, 837*b*
  management of, 837*b*
  microbiology of, 835–836, 837*b*
  nosocomial infections from, 836
  treatment of, 836–837
Sertaconazole, for superficial infection, 1533
Serum concentrations, antimicrobial therapy and, 1461
Serum sickness, diphtheria antitoxin for, 776
Serum tests, for urinary tract infections, 344–345
Set point, in HIV-1 infection, 665
Severe acute respiratory syndrome (SARS), 1148
  gastroenteritis and, 383, Human coronaviruses
Severe combined immunodeficiency (SCID) syndrome, 636–639
  autosomal recessive, 636–637
  characteristic infections in, 638
  clinical characteristics of, 637*t*
  definition of, 636

  - diagnosis of, 638
  - gene defects and inheritance pattern of, 636–637
  - *Pneumocystis jirovecii (carinii)* infection and, 1266
  - pneumonia in, 639
  - treatment of, 638–639
  - X-linked, 636
- Sewage, waste water, *Cryptosporidium* and, 1307
- Sexual abuse
  - infections associated with
    - *Chlamydia trachomatis* and, 1437*t*–1440*t*
    - *Neisseria gonorrhoeae*, 761
    - *Trichomonas vaginalis*, 1364–1365
  - pathogens in, 360
- Sexual activity, as risk factors, in urinary tract infections, 344
- Sexual contact, in HCV, 1137
- Sexually transmitted infections (STIs)
  - concurrent infections, 355
  - epididymitis and, 371
  - *Haemophilus ducreyi* (chancroid), 933
  - syndromes, 349–353
    - anal discharge, proctitis, proctocolitis, and enteritis, 350, 350*t*
    - asymptomatic, 349
    - dermatologic, 350*t*–351*t*, 352–353
    - discharge and dysuria, 349, 350*t*
    - genital ulcer and lymphadenopathy, 350–352, 350*t*
    - genitourinary, 349–352, 351*t*
    - pelvic pain, 350*t*, 352
    - pharyngeal, 350*t*–351*t*, 352

    - scrotal pain, 350*t*, 352
  - *Trichomonas vaginalis* and, 1365
- Sexually transmitted pathogens, 73*t*–74*t*, 75
- *SH2D1* gene, 643
- Sheep blood agar, 1424*t*
  - cerebrospinal fluid in, inoculation of, 1426
- Shell vial method, 1435
  - for CMV, 1435, 1441
  - for HSV, 1435
- Shellfish, paragonimiasis and, 1416
- *Shewanella* species, 858
- Shewanellaceae, 856
- Shiga-like toxin (STx), of *Escherichia coli*, 816
- Shiga toxin, 843
- *Shigella*, 1010
  - in foodborne disease, 398, 399*t*–405*t*
  - isolation of, media used for, 1425*t*
  - traveler's diarrhea from, 380
- *Shigella dysenteriae*, 1452
- *Shigella dysenteriae* type 1
  - hemolytic uremic syndrome and, 817
  - Shiga toxin, 843
- *Shigella flexneri*
  - prevalence of, 843
  - Reye-like syndrome from, 844
  - treatment for, 845
- *Shigella sonnei*
  - group childcare outbreaks of, 27–28

inflammatory enteritis from, 389
  prevalence of, 843
  Reye-like syndrome from, 844
  treatment for, 845
Shigella species, 842–846, 845*b*
  antimicrobial resistance of, 844–845
  bacteremia from, 844
  chromosomal virulence genes of, 843
  clinical manifestations of, 843–844
  description of, 842
  epidemiology of, 843
  extraintestinal infections of, 844
  immunity to, 842–843
  inflammatory enteritis from, 389, 389*t*
  ipaABCD and, 843
  laboratory findings and diagnosis of, 844
  mesenteric lymphadenitis from, 157
  musculoskeletal symptoms of, 844
  neurologic symptoms of, 844
  pathogenesis of, 842–843
  pathology of, 843
  plasmid virulence genes and, 843
  prevention of, 845–846
  serogroups of, 842
  shigellosis
    complications of, 844
    neonatal, 844
    uncomplicated, 843–844

  - surgical complications of, 844
  - treatment for, 844–845
  - vaccine development for, 845–846
  - vulvovaginitis due to, 844
- Short-incubation automated instrument method, for antimicrobial susceptibility testing, 1463
- Shunting procedures, for persistent pneumonia, 251–252
- SHV enzymes, in drug resistance, 1470
- Sickle cell disease
  - complement of, 628
  - persistent or recurrent pneumonia and, 255
- Sickle hemoglobinopathy, 643–646
  - bone and joint infections and, 645
  - central nervous system symptoms and, 644–645
  - epidemiology of, 644
  - etiologic agents of, 644
  - management and presumptive therapy of, 645
  - prevention of, 645–646
  - pulmonary symptoms of, 644
- Siderophores
  - fluorescent, in *Pseudomonas aeruginosa*, 866, 867*t*
  - *Klebsiella* and, 819
- , Signal transduction system, in *Staphylococcus aureus*, 693–694
- Silver nitrate
  - for eye infections, 1542*t*–1543*t*
  - for gonococcal ophthalmia neonatorum prevention, 765
- Silver sulfadiazine, for burn wound infections, 530, 531*t*
- Simeprevir, 1562

Simian T-lymphotropic viruses (STLVs), 1197

Sindbis virus, 1127

  arthritis from, 491

Sinus aspirate, transport systems and media inoculated routinely in, 1423*t*

Sinus aspiration, 232, 232*f*

Sinus histiocytosis with massive lymphadenopathy, lymphadenopathy from, 142

Sinus ostial obstruction, predisposing factors of, 230, 231*t*

Sinusitis, 230–234

  acute bacterial

    biphasic, 231

    Chlamydophila (Chlamydia) pneumoniae and, 906

    clinical presentations of, 231, 231*b*

    complications of, 233, 233*b*

    Haemophilus influenzae and, 929

    medical management of, 232–233, 233*t*

    persistence of symptoms in, 231

    severity of symptoms in, 231

    sinus aspiration and, 232

    worsening symptoms in, 231

  anaerobic Gram-negative bacilli causing, 1013

  in cancer, 589–590

  chronic, 232*t*, 233

  clinical manifestations of, 230–231

  diagnostic methods for, 231–232

  fungal, 590

  infections, cancer and, 589–590

  inflammatory edema, preseptal cellulitis caused by, 520–521
  major complications of, 233*b*
  medical management of, 232–233
  microbiology of, 232, 232*t*
  microsporidia associated with, 1334
  Moraxella catarrhalis causing, 864
  pathogenesis of, 230
  phaeohyphomycosis and, 1246
  recurrent, 233
  subacute, 231, 232*t*
  surgical management of, 233–234
SIRS, Systemic inflammatory response syndrome
Site of infection, in antimicrobial therapy, 1464
Skeletal muscle, enterovirus infections of, 1210
Skin, 447, 448*f*
  antiseptics for, 1548*t*
  barrier to infections, 523
  chronic meningitis in, 291–292
  darkening, visceral leishmaniasis causing, 1328–1329
  defense mechanism *vs*. pathogen virulence, 436
  host defense of, 528
  HSV infection in, 1058
  infections of, groups C and G streptococci causing, 737
  lesions, types of, 436, 437*t*
  microflora, 436
  by pathogens, transient colonization of, 436
  trauma to, 523–525
    infection risk and management following, 524*t*

Skin and soft tissue infections (SSTIs), 473
Skin colonization, of *Malassezia*, 1251
Skin infections, 353–357
  adnexal and follicular, 439–441
  anaerobic cocci causing, 1019
  anaerobic Gram-negative bacilli causing, 1013
  Aspergillus and, 587
  cancer and, 587
  Fusarium and, 1245
  hand and nail, 441
  in neonate, 552
  primary, 436
  prophylaxis/treatment for, 1546, 1547*t*
  in rodents, 538
  soft tissue, 442–444
  superficial, 437–439, 437*t*
    bacterial, 436–444
  ulcerative, 441–442
Skin lesions
  Blastomyces dermatitidis (blastomycosis) causing, 1272
  Erysipelothrix rhusiopathiae causing, 786
  in group childcare, 30–31
Skin snips, onchocerciasis causing, 1392
Skin test, for diskitis, 494
Skull
  congenital defects, in recurrent meningitis, 296
  fracture, in recurrent meningitis, 297
  fracture of, 525–526

- antibiotic prophylaxis for, 523*t*
- pathogens of, 523*t*
- lymphangiomatosis, in recurrent meningitis, 296

"Slapped cheek" rash, parvovirus B19 causing, 1116, 1117*f*

Sleep, chronic fatigue syndrome and, 1039

Sleep disorders, *Trypanosoma (Trypanozoon) brucei* infection and, 1368

Slim disease, 672

Slipped capital femoral epiphysis (SCFE), 187

Small bowel
- biopsy, for *Cyclospora* or *Cystoisospora*, 1322
- obstruction, vomiting and abdominal pain and, 173

Smoking, response to vaccines, 45

Snails
- liver and lung trematodes and, 1413
- schistosomiasis and, 1418

Social history, of recurrent infections, 615

Sodium fluoride, enteric illnesses caused by, 399*t*–405*t*

Sodium polyanetholesulfonate (SPS), 1423

Sodium stibogluconate
- adverse effects of, 1586
- treatment for
  - cutaneous infection, 1572
  - leishmaniasis, 1568
  - mucosal infection, 1572
  - visceral (kalaazar), 1572
  - visceral leishmaniasis, 1332

Sodium sulfacetamide, for conjunctivitis, 503

Sodoku (spirillary rat-bite fever), 966, 987

Sofosbuvir, 1562–1563

Sofosbuvir-Ledipasvir, 1562–1563

Soft palate, paralysis, *Corynebacterium diphtheriae* causing, 775

Soft tissue and fascia, diseases of, 188

Soft tissue diseases, limb pain from, 188

Soft tissue infections

- anaerobic cocci causing, 1019
- anaerobic Gram-negative bacilli causing, 1013
- groups C and G streptococci causing, 737
- *Kingella kingae* causing, 947
- in neonate, 552
- *Pseudomonas aeruginosa* causing, 868*t*
- recurrent, anatomic and physiologic abnormalities predisposing, 613*t*

Soft tissue necrosis, bite wounds and, 536

Soft tissue trauma, infections after, 523–525

- infection risk and management following, 524*t*

Solid organ transplant recipients, infections in, 567–573

- adenovirus, 570
- bacterial and fungal, 568–569
- cytomegalovirus, 569–570
- early, 568
- Epstein-Barr virus, 570
- HPIV infections and, 1156
- late, 568
- management and preventive measures for, 571–573, 572*t*
- opportunistic infections in, 571

  - *Pneumocystis jirovecii* pneumonia and, 571
  - postoperative and posttransplantation, 568
  - predisposing factors for, 567–568, 567*b*
    - intraoperative, 567, 567*b*
    - posttransplant, 567–568, 567*b*
    - pretransplant, 567, 567*b*
  - pretransplantation evaluation in, 571–572, 572*t*
  - screening tests for, 572*t*
  - timing of, 568, 568*t*
  - *Toxoplasma gondii* infection and, 1352, 1358, 1361
  - toxoplasmosis and, 571
  - tuberculosis and, 571
  - viral, 569–571
    - common community-acquired, 571
- Somnolence, *Trypanosoma (Trypanozoon) brucei* infection and, 1368
- Sore throat
  - respiratory tract diphtheria and, 774
  - in subacute or chronic sinusitis, 231
- Southeastern tick-associated rash illness (STARI), 542–543
  - agents, vectors, and geographic distribution of, 543*t*
  - clinical and laboratory manifestations of, 544*t*–545*t*
- Special hosts, infectious complications in, 643–651
- Species, virus, 1045
- Specificity, 1, 2*t*
- Spectinomycin, for *Neisseria gonorrhoeae* infections, 764
- Sphenoid sinus, recurrent meningitis and, 300*f*
- Spherules, 1276, 1276*f*
- Sphingobacteriaceae, 856

Sphingobacterium species, 858
Sphingomonadaceae, 856
Sphingomonas paucimobilis, 865
Sphingomonas species, 858
Spin-amplified culture, 1435
Spinal epidural abscess, 190
Spinal fusion, surgical site infections in
  clinical manifestations and laboratory diagnosis of, 599
  epidemiology and pathogenesis of, 598
  management and outcome of, 599
  prevention of, 600
Spinal muscular atrophy
  hypotonia from, 182*t*–183*t*
  infant botulism *versus*, 1003*t*
Spinosad
  for lice infestation, 1572
  for pediculosis, 1296
Spiramycin
  adverse effects of, 1586
  for protozoan infection treatment, 1570
  for *Toxoplasma gondii*, 1353, 1359, 1360*t*
Spirilla, definition of, 690
Spirillum, 690
Spirillum minus, 160, 966, 987
Spirochetal infections, generalized lymphadenopathy from, 131
Spirochetes, 690, 969
Spleen
  anatomy and function of, 128

  platelet destruction in, 1457
  visceral leishmaniasis and, 1328–1329
Splenectomy
  for indication, of HIV infection, 673
  infections after, 525
    pathogens and recommended prophylaxis following, 523*t*
Splenic abscess, 434–435
Splenic function, predominant pathogens infecting children and, 580*t*
Splenic rupture, after trauma, infections and, 525
Splenomegaly
  EBV infection and, 1090
  murine typhus *(Rickettsia typhi)* and, 959
Spondylodiskitis, *Kingella kingae* causing, 946
Spondylolisthesis, 190
Spondylosis, 190
Spontaneous abortion, viral infections causing, 558
Sporangiophores, 1247–1248
Sporangium, 1247–1248
Spores
  of *Clostridium botulinum*, 1000
  of *Clostridium difficile*, 1008
  of *Clostridium tetani*, 995
  of microsporidia, 1334, 1335*f*
Sporogony, 1334
Sporothrix, chronic meningitis from, 292*t*
Sporothrix schenckii
  arthritis from, 492

  cat bite infection from, 533–534
  lymphangitis from, 162
Sporothrix schenckii complex (sporotrichosis), 1253–1255, 1255*b*
  arthritis from, 1254
  clinical manifestations of, 1254
  cutaneous infections, 1254
  diagnosis of, 1254
  epidemiology of, 1254
  “fixed” infections, 1254
  , lymphocutaneous, 1254
  meningitis and, 1254
  in Peru, 1254
  pneumonia from, 1254
  prevention of infection, 1255
  pulmonary infections, 1254
  treatment of, 1254–1255
Sporotrichoid spread, 461–462
Sporozoites
  of *Plasmodium*, 1342–1343, 1342*f*
  of *Pneumocystis jirovecii (carinii)*, 1266
  of *Sarcocystis*, 1350–1351, 1351*f*
  of *Toxoplasma gondii*, 1352–1353
Sporulation, adventitious, 1241
Spot agglutination assay, for Epstein-Barr virus, 1441
Spot map, 7
Sputum
  collection of, 1426–1427
  contamination, in nontypable *Haemophilus influenzae* detection,

929
induction, 800
paragonimiasis and, 1417
for *Pneumocystis jirovecii (carinii)* detection, 1267, 1267*f*
sample in pneumonia, 242–243
transport systems and media inoculated routinely in, 1423*t*
Squalene epoxidase inhibitors, 1533
St. Louis encephalitis virus, 1131
aseptic meningitis and, 302
diagnosis/detection of, 1445
encephalitis from, 311
optimal tests for, 1437*t*–1440*t*
Stainer-Scholte medium, 1424*t*
Standard deviation, 2*t*, 5
Standard error (SE), 2*t*, 5
Standard precautions, 15, 16*t*
Staphylococcal chromosome cassette *mec* (SCC*mec)*, 694
Staphylococcal lid disease, 508, 508*f*
Staphylococcal scalded skin syndrome (SSSS), 449, 450*f*
Staphylococci
conjunctivitis due to, 501
isolation of, media used for, 1425*t*
Staphylococcus, coagulase-negative (CoNS), 706–712, 712*b*
antibiotic treatment for, 710–711
bloodstream infection from, 708–709
clinical manifestations of, 708–710
description of, 707
epidemiology of, 708

- intravascular catheter-related infection from, 708–709
- pathogenesis of, 707–708, 707*f*
- peritonitis from, 710
- prevention of, 711

Staphylococcus (staphylococci), coagulase-negative (CONS), peritonitis from, 424

Staphylococcus albus, 707

Staphylococcus aureus, 691–706, 769, 834

- abscess, 466, 695–696, 695*f*
  - brain, 700–701
  - lung, 698
  - muscle of, 697
  - spinal epidural, 701
  - viscera of, 697
- acute bacterial sinusitis from, 232, 232*t*
- acute bilateral lymphadenopathy lymphadenitis from, 139–140, 140*f*
- acute mastoiditis from, 227
- acute otitis media from, 217
- animal bite infection from, 532
- antimicrobial resistance of, 693–694
  - β–lactams resistance, 1470–1471
  - macrolides, 1473
  - rifampin, 1473
  - vancomycin-resistant (VRSA), 1472
- antimicrobial susceptibility testing for, 1428, 1428*t*
- bacterial infections from, in neonate, 550
- bacterial myositis from, 473–474

bacterial tracheitis from, 167
blistering distal dactylitis from, 441
in blood, 1425
brain abscess from, 329
breast abscess from, 468–469
bullous impetigo from, 437, 438*f*
burn wound infection from, 528–529
cancer and, 580
capsule and cell wall of, 693
cardiovascular infections from, 698–700
catheter-related peritonitis from, 424
cellulitis from, 443
central nervous system infections from, 700–701
cervical lymphadenitis from, 136
Chédiak-Higashi syndrome from, 635
chronic granulomatous disease from, 255
chronic mastoiditis from, 229
clinical manifestations of, 695–702
colonization of, 694
community-associated, 694–695
  empiric therapy for, 705, 705*f*
community-associated methicillin-resistant (CA-MRSA), 523–525
  acute osteomyelitis from, 480
  complicated parapneumonic effusion from, 245
  neonatal osteomyelitis from, 483
  wound cellulitis from, 523–525
dacryoadenitis from, 519
device-related infections from, 701

diskitis from, 493
empyema or pleural effusion from, 245
endocarditis from, management of, 268
epidemiology of, 694–695
epidural abscess (cranial and spinal) from, 330
flaccid bullae and, 449
in foodborne disease, 398, 399*t*–405*t*
furuncle from, 440
genetic basis of, 693–694
healthcare-associated infections from, 694
heart-lung transplantation and, 569
heart transplantation and, 569
hemolysis and anemia from, 1451

        standard media and test conditions in, 1427–1428, 1428*t*–1430*t*
        Staphylococcus aureus in, 1428
        Streptococcus pneumoniae in, 1428–1430
    of bacteria
        breakpoint establishment of, 1474
        methods of, 1474–1475, 1475*f*
        resistance detection of, 1474–1475
    of viruses, HSV and, 1435
Suturing, of bite wounds, 535
Swabs
    for *Chlamydia trachomatis*, 1446
    in collection methods and transport media, 1422*t*
    for viral infection diagnosis, 1434
Sweat gland abscesses, 469
Sweet syndrome, 464
Swimmer's ear, 223
    Pseudomonas aeruginosa causing, 868*t*
    treatment for, in normal host, 870
Swimming
    Giardia intestinalis (giardiasis) prevention and, 1320
    Naegleria fowleri infections and, 1337
Swimming pool
    Naegleria fowleri infections and, 1337
        chlorine disinfection in, for prevention of, 1338
    pharyngoconjunctival fever from, 502

- water contamination, *Cryptosporidium* in, 1307
- water contamination in, *Acanthamoeba* and, 1339

Swine influenza viruses, 1182, 1189

Swollen belly syndrome, 1374*t*, 1379

Swyer-James syndrome, 254

Sycosis barbae, 437*t*

Sydenham chorea (St. Vitus dance), 720

Symmetric peripheral gangrene, 453–454

Syncephalastrum, 1247–1248

Syndrome of congenital infection, 558, 558*t*

Syndrome of inappropriate secretion of antidiuretic hormone (SIADH), 322
- varicella in cancer causing, 1068

Syndromic panels, 1434

Synergy
- in anaerobic cocci, 1018
- antimicrobial combinations and, 1465–1466

Synovial fluid
- examination, for musculoskeletal pain, 185
- *Mycoplasma pneumoniae* and, 1025
- in pyogenic arthritis, 488
- specimen-specific isolation methods in, 1427
- in transient synovitis, 496

Syphilis, 969–976
- acquired, 970–971
- cardiovascular, 970
- congenital, 971–972
- endemic, 969, 977

  in genital ulcer and lymphadenopathy, 352
  meningeal, 970
  mother-to-child transmission of, 971
  in refugee and internationally adopted children, 36
  venereal, 969
Systematic error, 4
Systemic inflammatory response syndrome (SIRS), 98–102, 99*t*, 523
  clinical signs of, 100
  definition of, 98, 99*b*, 100*t*
  etiology of, 98–99
  future considerations of, 102
  laboratory findings of, 100
  , management of, 100–102
    antimicrobial therapy, 100–101, 101*t*
    corticosteroids, 101–102
    intravenous immunoglobulin therapy, 101
    supportive care, 101
  pathophysiology of, 99–100
Systemic lupus erythematosus (SLE)
  as diagnostic criteria, 184–185
  limb pain and, 186, 187*t*
Systemic-onset juvenile idiopathic arthritis, MAS from, 108

T

α/β T-cell compartment, 636
T cells, 635–636
T helper 1 immunity, impaired, 641–642
T helper 17 immunity, impaired, 642

T lymphocyte-derived tumor necrosis factor, in granulomatous hepatitis, 416–417

T-lymphocyte immunity, measles-specific, 1174

T lymphocytes, 90*f*, 92–93, 92*t*

- abnormalities of, persistent or recurrent pneumonia and, 255
- antigen presentation of, 44
- CD4+ (helper), 44
  - counts in HIV infection, 675
  - *Cryptococcus neoformans* and, 1256
  - decline in HIV infection, 673
  - in HIV-1 infection, 665
  - low counts in *Pneumocystis jirovecii* infection and, 1266–1267
  - *Toxoplasma gondii* infection and, 1353–1354
- CD8, 636
- CD8$^+$, *Toxoplasma gondii* infection and, 1353–1354
- deficiency
  - detection of, 617*t*
  - in pneumonia, 257*t*
- enterovirus infections and, 1206
- *Giardia intestinalis* and, 1318
- *Histoplasma capsulatum* and, 1260
- immunopathologic consequences of HIV-1 infection on, 666*b*–667*b*
- in *Leishmania* infections, 1323–1324
- memory, VZV infection and, 1066
- VZV infection and, 1065

Tabes dorsalis, tertiary syphilis causing, 970

Tachycardia

Corynebacterium diphtheriae and, 775
definition of, 99*b*
orthostatic, chronic fatigue syndrome causing, 1039
sepsis and, 100
Tachypnea, 168–171
in pneumonia, 241
sepsis and, 100
Tachyzoites, of *Toxoplasma gondii*, 1352–1353, 1356
Taenia, neurocysticercosis and, 329
Taenia asiatica, 1397–1404
life cycle of, 1397–1398, 1398*f*
taeniasis, 1397–1399
clinical manifestations of, 1398
epidemiology of, 1397–1398
laboratory findings and diagnostic tests of, 1399
Taenia (Multiceps) multiceps, 1410–1411, 1411*b*, 1411*f*
Taenia saginata, 1293*t*, 1397–1404
life cycle of, 1397–1398, 1398*f*
T. solium and, 1397–1404, 1397*f*
taeniasis, 1397–1399
clinical manifestations of, 1398
epidemiology of, 1397–1398
laboratory findings and diagnostic tests of, 1399
Taenia serialis (coenurosis), 1397, 1410–1411, 1411*b*, 1411*f*
Taenia solium, 1293*t*, 1397–1404, 1397*f*
autoinfection of, 1399
chronic meningitis from, 292–293
cysticercosis, 1293, 1293*t*, 1399–1404

  associated syndromes of, 1401
  calcifications from, 1400*f*, 1401, 1402*t*
  clinical manifestations of, 1400–1401
  diagnosis of, 1400*b*, 1401–1402
  epidemiology of, 1399–1400
  mixed forms of, 1401
  muscle and, 1400*f*
  pathogenesis of, 1399–1400
  prevention for, 1404
  treatment and prognosis of, 1402–1403
  vaccine for, 1404
eosinophilic meningitis from, 340*t*, 342
epidemiology and life cycle of, 1397–1398, 1398*f*
neurocysticercosis, 1399
  diagnosis of, 1401
  extraparenchymal, 1401
  ocular, 1400*f*, 1401, 1402*t*
  parenchymal, 1400*f*, 1401, 1402*t*
  spinal, 1402*t*
  subarachnoid, 1400*f*, 1401–1402
  treatment and prognosis of, 1402–1403, 1402*t*
  ventricular, 1401, 1402*t*
T. saginata and, 1397–1404, 1397*f*
taeniasis, 1397–1399
  clinical manifestations of, 1398–1399
  diagnosis and management of, 1397*b*
  laboratory findings and diagnostic tests for, 1399
  treatment for, 1399

Taenia species, eosinophilia from, 1454–1456

Tamm-Horsfall protein, 343

Tanapox, 1053

Tanapox virus, 1049*t*, 1053

Tapeworms

  of dog, or double-pored, 1395, 1396*f*

  of fish or broad, 1394

  of rodent, 1395

  treatment of infections for, 1571

Target lesions, 108

Tattoos, infections from, 523

  risk and management following, 524*t*

Tatumella, 831

Tazobactam

  dosing of, for impaired renal function, 1490*t*–1498*t*

  pharmacokinetics of, 1499*t*–1505*t*

Tdap/Td, in adolescents, contraindications,precautions, and reasons to defer, 60

Tears, secretory rate of, 497–498

Technetium phosphate radionuclide scan, for pyogenic arthritis, 488

Tedizolid

  dosage for, 1527*t*–1530*t*

  dosing of, for impaired renal function, 1490*t*–1498*t*

  spectrum of activity of, 1506*t*–1511*t*

  for *Staphylococcus aureus* infection, 704

Teeth, Hutchinson, 972

Telavancin, 1516

  pharmacokinetics of, 1499*t*–1505*t*
  spectrum of activity of, 1506*t*–1511*t*
  for *Staphylococcus aureus* infection, 704–705
Telbivudine, 1563
Telithromycin, 1517–1518
  dosage for, 1527*t*–1530*t*
  for impaired renal function, 1490*t*–1498*t*
  pharmacokinetics of, 1499*t*–1505*t*
  spectrum of activity of, 1506*t*–1511*t*
  for *Ureaplasma, urealyticum* infection, 1032
TEM enzymes, in drug resistance, 1470
Temperature
  axillary readings of, 94
  diurnal fluctuation of, 94
  oral, 94
  rectal, 94
    normal by age/gender, 118
Temporal bone, anomalies, in recurrent meningitis, 296*b*, 300
Temporal lobe abscesses, 329
  complications of, 338
Tendon reflexes, deep, 190
Tenesmus, 350
Tenofovir, 683
  dosing of, 1490*t*–1498*t*
Tenofovir diphosphate, 1563–1564
Tenofovir disoproxil fumarate, 1563–1564
Tensilon test, 1003
Teratogenicity, ribavirin and, 1141

Terbinafine
  dosing of, 1490*t*–1498*t*
  for *Sporothrix schenckii* complex (sporotrichosis), 1254–1255
  for superficial infection treatment, 1532*t*, 1533
  for tinea capitis, 1284
Terconazole, 1533
Terminal fragment length polymorphism (*t*FLP), 1251
Terranova, 1385
Tetanolysin, 995–996
Tetanospasmin, 995–996
  mechanism of action of, 995–996
  paralysis from, 996
Tetanus immune globulin, 39
Tetanus prophylaxis, for bite wound infection, 535
Tetracycline(s), 1473–1474, 1519–1520, 1572
  adverse effects of, 1586
  antibacterial agents with antiprotozoan activity, 1570
  dosage for, 1527*t*–1530*t*
    impaired renal function, 1490*t*–1498*t*
  mechanism of action of, 1474
  pharmacokinetics of, 1499*t*–1505*t*
  resistance to, 1468*t*, 1473–1474
  spectrum of activity of, 1473–1474, 1506*t*–1511*t*
  treatment for
    balantidiasis *(Balantidium coli)*, 1572
    Balantioides coli infection, 1303–1305
    Bartonella bacilliformis infection, 968
    bite wound infections, 536

    - *Borrelia* species infection, 986
    - *Chlamydophila psittaci* infection, 915
    - eye infections, 1542*t*–1543*t*
    - murine typhus *(Rickettsia typhi)*, 960
    - for *Mycoplasma hominis* infection, 1029
    - *P. vivax* infection, 1572
    - *Plasmodium* infections, 1345, 1345*t*–1346*t*
    - *Rickettsia prowazekii* infection, 959
    - severe malaria, 1572
    - skin wound infections, 523–525
    - *Staphylococcus aureus* infection, 704
    - tetanus, 997*t*
- Tetracycline-class antibiotics
  - contraindicated, during pregnancy, 956
  - for Rocky Mountain spotted fever *(Rickettsia rickettsii)*, 955
  - during tooth crown calcification, 955–956
- Th1-associated immune responses, 1276–1277
- Thallium, enteric illnesses caused by, 399*t*–405*t*
- Thayer-Martin modified agar, 1424*t*
- Thermoregulation, in fever, 94
- Thermoregulatory neurons, 93–94
- Thiabendazole
  - for cutaneous larva migrans, 1385
  - for *Strongyloides fuelleborni* infections, 1376
  - for *Strongyloides stercoralis* infections, 1376
- Thoracic trauma, 526
  - infection risk and management following, 524*t*
  - pathogens and recommended prophylaxis following, 523*t*

Throat culture, for pharyngitis, 205

Throat swab

  in respiratory tract, 1426

  transport systems and media inoculated routinely in, 1423*t*

Thrombin, generation of, in sepsis, 100

Thrombocytopenia, 1458

  Babesia infections and, 1300, 1301*f*

  causes of, 1458*b*

  EBV infection and, 1094

  Ehrlichia and *Anaplasma* infections and, 921

  HIV infection and, 673

  Plasmodium infections and, 1344

  R. felis and, 960

  varicella complication and, 1067

Thrombocytopenia syndrome, severe fever with, 1134*t*

Thrombocytopenic purpura

  acquired rubella and, 1147

  congenital rubella and, 1145

Thrombocytosis, 1457–1458, 1457*t*

Thrombocytosis, in Kawasaki disease, 1035

Thrombophlebitis

  septic, Septic thrombophlebitis

  superficial, 270

  suppurative, burn and, 529

Thrombopoietin, 1457

Thrombosis, burn wound infections and, 528

Thrush, 194, 1232, 1232*f*

Thymus

  anatomy and function of, 128
  destruction in HIV infection, 675
  developmental changes of, 129
, Thyroid disorders, congenital rubella causing, 1145–1146
Thyroid gland, masses, 144
Thyroiditis, 144
  subacute (de Quervain), 144
Ticarcillin, 1515
  dosing of, for impaired renal function, 1490*t*–1498*t*
  for eye infections, 1543*t*
  pharmacokinetics of, 1499*t*–1505*t*
  spectrum of activity of, 1506*t*–1511*t*
Ticarcillin-clavulanate
  dosage for, 1527*t*–1531*t*
  spectrum of activity of, 1506*t*–1511*t*
Tick bite fever, African, 963–966
Tick paralysis, 183*t*–184*t*, 542
Tickborne, *Borrelia* species (relapsing fever) and, 986
Tickborne diseases, *Babesia* (babesiosis) and, 1298
Tickborne encephalitis virus (TBEV), 1130
  agents, vectors, and geographic distribution of, 543*t*
  aseptic meningitis from, 302
  clinical and laboratory manifestations of, 544*t*–545*t*
  prevention of, 546
Tickborne encephalitis virus vaccine, 82
Tickborne infections, 542–546, 543*t*
  clinical manifestations, 542–543, 544*t*–545*t*
  diagnosis of, 543–545

- epidemiology of, 542
- granulomatous hepatitis and, 417
- pathogenesis of, 542
- prevention of, 546
- treatment for, 545–546

Tickborne relapsing fever
- agents, vectors, and geographic distribution of, 543*t*
- clinical and laboratory manifestations of, 544*t*–545*t*

Tickborne spotted fever, Rocky Mountain spotted fever *(Rickettsia rickettsii)* and, 952–953

Ticks, 542, 985
- hard, 542
- life cycle of, 542
- prevention, of *Borrelia burgdorferi* (Lyme disease), 985
- Rocky Mountain spotted fever *(Rickettsia rickettsii)* and, 956–957
- soft-bodied, 542
- as vector, of Colorado tick fever, 1119–1121

Tietze syndrome, 191

Tigecycline, 1473–1474, 1520
- dosing of, for impaired renal function, 1490*t*–1498*t*
- pharmacokinetics of, 1499*t*–1505*t*
- resistance to, 1473–1474
- spectrum of activity of, 1506*t*–1511*t*
- for *Staphylococcus aureus* infection, 704
- for *Stenotrophomonas maltophilia*, 874

Time-dependent drugs, 1487

Time-resolved, cryptate-emission [TRACE] immunoassay, 1450

Time-to-event analyses, 3, 5

Tin, enteric illnesses caused by, 399*t*–405*t*

Tinea, 1282

Tinea capitis, 1282–1284, 1283*b*

  clinical manifestations of, 1282–1284, 1283*f*

  in group childcare, 31

  microbiology and epidemiology of, 1282

  treatment of, 1284

Tinea corporis (ringworm), 1284–1285, 1285*b*

Tinea cruris (jock itch), 1285

Tinea gladiatorum, 1284–1285

Tinea nigra, 1286–1287

Tinea pedis (athlete's foot), 1284

Tinea unguium (onychomycosis), 1286

Tinea versicolor (pityriasis versicolor), 1286, 1286*b*

Tinidazole

  adverse effects of, 1586

  for *Giardia intestinalis* (giardiasis), 1319, 1320*t*

  for protozoan infection, 1567

Tipranavir, 682*t*, 1490*t*–1498*t*

Tissue concentrations, in antimicrobial therapy, 1461

Tissue flukes, 1293

Tissue invasive disease, 569

Tissue necrosis, 470

Tissue nematodes, Nematodes (roundworms)

Tissue specimens, for parasite, laboratory diagnosis of, 1433

TNF-α receptor 1 protein (TNFR1), 127

TNF inhibitors, *Mycobacterium tuberculosis* and, 652

TNFRSFIA genes, 122–123

Tobramycin, 1521
  dosage for, 1527*t*–1531*t*
  inhaled, 650
  pharmacokinetics of, 1499*t*–1505*t*
  spectrum of activity of, 1506*t*–1511*t*
  treatment for
    eye infections, 1542*t*–1543*t*
    impaired renal function, 1490*t*–1498*t*
Togaviridae, 1045*t*, 1126–1128
  arthritis from, 491*b*
  infections, 1046*t*
Toll-like receptors, 86–87, 96*t*
  in *Pseudomonas aeruginosa*, 866–867
  in urinary tract infections, 343
Tolnaftate, for superficial fungal infections, 1533
Tonsillar membrane, respiratory tract diphtheria and, 774
Tonsillectomy, for PFAPA, 125
Tonsillitis
  adenoviruses causing, 1099
  anaerobic Gram-negative bacilli causing, 1013
Tooth
  demineralization, 193
  infections, 193
Toothpick puncture injury, 526
Topical antifungal agents, 1532–1533
Topical antimicrobial agents, 1541–1550
  characteristics of, 1548*b*
  treatment for

    - burns, 530, 531*t*, 1546–1550, 1549*t*–1550*t*
    - ear infections, 1544–1546, 1545*t*
    - eye infections, 1541–1544, 1542*t*–1543*t*
    - skin infections, 1546, 1547*t*
- Topoisomerase IV, *Salmonella* and, 840
- TORCH serologic screen, 409
- Toscana virus (TOSV), aseptic meningitis from, 302
- Tourniquet test, for dengue viruses, 1129
- Toxic encephalopathy
  - *Proteus* causing, 834
  - *Shigella* causing, 844
- Toxic epidermal necrolysis (TEN), 108
  - erythema multiforme *vs*., 111*t*
  - Stevens-Johnson syndrome *vs*., 111*t*
- Toxic shock-like syndrome, groups C and G streptococci causing, 736
- Toxic shock syndrome, 41
  - comparative features of, 111*t*
  - necrotizing fasciitis and, 525
  - staphylococcal, 702, 702*b*
  - streptococcal, 718, 718*b*
- Toxic shock syndrome toxin-1 (TSST-1), staphylococcal toxic shock associated with, 108
- α-Toxin, 1009–1010
- Toxins
  - acute hepatitis and, 413
  - chronic hepatitis from, 416
  - in foodborne disease, 398

granulomatous hepatitis from, 418

Toxocara (toxocariasis)

clinical features of, 1382–1383

covert, 1381–1382

diagnosis of, 1383, 1384*f*

eggs of, 1382, 1382*f*

larvae of, 1383*f*

life cycle of, 1382, 1382*f*

medical ecology of, 1383–1384

ocular larva migrans and, 1381–1384

prevention of, 1383–1384

treatment of, 1383–1384

visceral larva migrans from, 1381–1384

Toxocara canis, 325, 1293*t*, 1381–1384

clinical features of, 1383

diagnosis of, 1383

eosinophilia from, 1454–1456

eosinophilic meningitis from, 340*t*, 342

granulomatous hepatitis from, 417

life cycle of, 1382, 1382*f*

retinitis from, 510*t*, 513

treatment of, 1383

Toxocara cati, 1381–1384

clinical features of, 1383

diagnosis of, 1383

eosinophilia from, 1454–1456

life cycle of, 1382, 1382*f*

treatment of, 1383

Toxocariasis, ocular, 513

Toxoplasma

  chronic fatigue syndrome from, 1038*b*

  congenital infections, characteristic manifestations of, 548*t*

Toxoplasma gondii (toxoplasmosis), 1352–1364

  acute infection of, 1353

    diagnosis of, 1356

    prevention of, 1361

    risk factors for, 1353

  antibodies and, 1352

  asymptomatic infection of, 1352, 1354

  atovaquone treatment for, 1569

  bradyzoites of, 1352–1353

  brain abscess from, 329, 1356

  cancer and, 581

  chorioretinitis and

    clinical manifestations of, 1354, 1355*f*

    diagnosis of, 1356

    examination of, 1354

    prevention of relapses in, 1360*t*, 1361

  chronic infection of, 1352

    diagnosis of, 1356

    in immunocompetent children, 1355–1356

    reactivation of, 1352, 1354

  chronic meningitis from, 291

  clinical manifestations of, 1354–1356, 1363*b*

    chronic infection in immunocompetent children, 1355–1356

    congenital toxoplasmosis, 1354–1356, 1355*b*, 1355*f*

congenital toxoplasmosis, 1354–1356
  chorioretinitis and, 1355, 1355*f*
  clinical manifestations of, 1355, 1355*b*, 1355*f*
  epidemiology of, 1353
  incidence of, 1353
  in neonate, 1357
  treatment for, 1360*t*
diagnosis of, 1356–1359, 1363*b*
  AC/HS test, 1357
  in acute and chronic infection, 1356
  in immunocompetent children, 1357–1358
  in immunocompromised pediatric patients, 1358–1359
  in neonate, 1357, 1358*b*
  in pregnancy, 1356–1357
  serologic tests for, 1356
  toxoplasmosis and, 1356
encephalitis and, 312, 1355
  diagnosis of, 1356
  prophylaxis for, 1361
enteric illnesses caused by, 399*t*–405*t*
eosinophilic meningitis from, 340*t*
epidemiology of, 1353, 1353*f*–1354*f*, 1363*b*
genome of, 1352
immune response of, 1353–1354
immunocompromised hosts
  clinical manifestations of, 1356
  diagnosis of, 1358–1359
  immune response and, 1353–1354

  prophylaxis against reactivation of latent infection, 1361
  treatment for, 1359, 1361*t*
laboratory testing of, 318*t*–321*t*
life cycle of, 1352–1353, 1353*f*
lymphadenopathy and, 1354, 1357
  generalized lymphadenopathy, 1354
oocyst of, 1352, 1353*f*
parasitic myositis from, 475
pathogen, 1352–1353
pathogenesis of, 1353–1354
in pregnancy, 1353
  clinical manifestation of, 1354–1355
  diagnosis of, 1356–1357
  transmission rate of, 1353, 1354*f*
  treatment for, 1359, 1359*f*, 1360*t*
prevention of, 1360–1361
  primary infection, 1360–1361, 1362*t*–1363*t*
  reactivation of latent infection, 1361
primary infection in immunocompetent children, adults, and pregnant women, 1354
, reactivation, of infections, 1352, 1354
  clinical manifestation of, 1356
  prevention of, 1361
retinitis from, 510–511, 510*t*, 511*f*
solid organ transplant recipients and, 571
sporozoites of, 1352–1353
tachyzoites of, 1352–1353, 1356
in tissue specimens, 1433

- treatment for, 1359, 1360*t*, 1363*b*
  - immunocompetent children, 1359, 1361*t*
  - immunocompromised children, 1359, 1361*t*
  - neonate, 1359, 1362*f*
  - pregnant women, 1359, 1359*f*, 1360*t*

Toxoplasmosis
- infections in hematopoietic stem cell transplant recipients, 576
- subacute or chronic unilateral lymphadenitis from, 141

Trabulsiella, 831

Tracheal aspiration, for diagnosis of pneumonia, 242–243

Tracheal bronchus, 252

Tracheitis
- bacterial, 167
- *Staphylococcus aureus* causing, 698

Tracheobronchial tree, congenital cystic anomalies of, pneumonia and, 252

Tracheobronchitis
- in burn patients, 529
- necrotizing and exudative tracheobronchitis, HSV causing, 1059

Tracheoesophageal fistula, H-type, persistent or recurrent pneumonia and, 255

Tracheostomy, for infant botulism, 1004

Trachipleistophora, 1335*t*

Trachoma, *Chlamydia trachomatis* and, 913

Transcription-mediated amplification (TMA), for *Trichomonas vaginalis*, 357

Transesophageal echocardiography (TEE), for endocarditis, 265

β_2-Transferrin assay, in CSF, for recurrent meningitis, 299

Transfusion-acquired HCV infection, 1137

Transfusion transmitted virus, 1228

Transient anicteric hepatitis, rubeola virus infection (measles) and, 1172

Transient hypogammaglobulinemia of infancy, 619*t*, 623–624, 624*b*

Transient mild thrombocytopenia, 1458

Transient synovitis, 186, 187*t*, 496–497

- clinical manifestations of, 496
- diagnosis of, 496
- differential diagnosis of, 496–497
- epidemiology of, 496
- etiology of, 496
- prognosis of, 497
- treatment for, 497

Transmission-based precautions, 15–16, 17*t*–18*t*

Transmission of infections, 11–12

- horizontal, 11
- modes, 11

Transplacental transmission, of West Nile virus, 1130

Transplant recipients

- adenoviruses infection in, 1099
- infections in, 567–573
  - adenovirus in, 570
  - *Aspergillus* infections and, 1240–1241
  - CMV infection and, Cytomegalovirus
  - cytomegalovirus in, 569–570
  - Epstein-Barr virus in, 570
  - immunization after, 572–573

    - *Toxoplasma gondii*, 1352, 1361
    - varicella and, 1068
- Transport media
  - bacteria in, 1422, 1422*t*
  - viral, 1434
- Transporters, of drugs, 1484–1485
- Transposons, in acquired drug resistance, 1469
- Transtracheal aspirate, transport systems and media inoculated routinely in, 1423*t*
- Transudate, 244
- Transverse myelitis, 183*t*–184*t*, 326
  - acute, enterovirus infections causing, 1210
  - diagnosis of, 326
  - etiologies of, 323*t*
  - herpes zoster and, 1068
  - incidence of, 326
  - MRI for, 327*f*
  - treatment of, 326
  - varicella with, 1067
- Trauma
  - adverse effects on host defense, 523
  - chronic fatigue syndrome and, 1040
  - infection following, 522–526
    - antibiotic therapy for, 523, 524*t*
    - incidence of, 522
    - management of, 523
    - pathogenesis, 523, 523*t*
    - risk factors for, 523

Travel-associated rickettsioses, 963–966

Travelers, hepatitis A virus infection in, 1214

Travelers, protection of, 79–85

- diarrhea, Diarrhea, travelers'
- *E. coli* infections and, 818
- emerging infectious disease, 85
- immunization, 80
  - poliovirus vaccine, 1204
  - routine, 80–81, 80*t*
- immunocompromised, 85
- in malaria, 83
  - chemoprophylaxis, 79*b*, 83
  - protective measures, 83, 83*b*
- preparation for, 79–83
  - general advice, 79–80, 80*b*
  - recommended vaccines for, 81–83, 82*t*
- return from, 85

Trematodes, 1293, 1293*t*

- blood, 1418–1421
- intestinal, 1412–1413, 1412*t*
- in liver and lung, 1413, 1414*t*

Trench mouth, 194

Treponema, 690

- congenital infections, characteristic manifestations of, 548*t*

Treponema carateum, 969, 977

Treponema pallidum (syphilis), 454, 969–976, 975*b*–976*b*

- acquired syphilis from, 970–971
  - in children, 974

anal discharge, proctitis, proctocolitis, and enteritis syndrome from, 350

anterior uveitis from, 510

antigenic lipoproteins in, 969

aseptic meningitis from, 303

cardiovascular syphilis, 970

in child abuse, 375

chronic meningitis from, 289

  clinical manifestations of, 289

  diagnosis of, 289

  epidemiology of, 289

  laboratory findings of, 289

  pathogenesis of, 289

clinical manifestations of, 970–972

congenital syphilis from, 971–972

  assessment and management of, 973*f*

  definition of, 972–974

  diagnosis of, 972–974

  early disease, 971–972

  evaluation for, 974

  late disease, 972

  testing considerations of, 974

diagnosis/detection of, 972–974

  antibody tests, 972

  nontreponemal tests, 972

  organisms, tests for, 972

  treponemal tests, 972

endothelial cells and, 969

  - eosinophilic meningitis from, 340*t*
  - epidemiology of, 969–970
  - etiologic agents, in inguinal lymphadenopathy with genital ulcers, 353
  - general paresis from, 970
  - generalized lymphadenopathy from, 970
  - gummas and, 969
  - human immunodeficiency virus and, 970–971
  - incubation period of, 970
  - laboratory findings of, 318*t*–321*t*
  - latent syphilis from, 970
  - meningeal, 970
  - meningitis from, 970
  - microbiology and pathogenesis of, 969
  - mother-to-child transmission of, 971
  - neurosyphilis from, 970
  - in pregnancy, 970
  - prevention of, 975
  - primary syphilis from, 970
  - rare outer membrane proteins (TROMP) and, 969
  - reagin antibody and, 1459*t*
  - secondary syphilis from, 970
  - tabes dorsalis from, 970
  - tertiary syphilis from, 970
  - treatment and follow-up of, 974–975, 975*t*
- *Treponema pallidum* particle agglutination test (TP-PA), 972
- *Treponema pallidum* subsp. *endemicum*, 969, 977
- *Treponema pallidum* subsp. *pallidum*, 969

Treponema pallidum subsp. *pertenue*, yaws, 976–977
  clinical manifestations of, 976
  diagnosis of, 977
  treatment of, 977
Treponema species, 976–977
  endemic syphilis (bejel), 977
  pinta, 977
  treatment of, 977
  yaws, 976–977
Treponemataceae, genera included, 690
Triatoma infestans, 1370
Triatomine bug, 1370*f*
Triazole
  for *Cryptococcus* infection, 1258
  for systemic fungal infections, 1535*t*
Trichinella murrelli, 1386
Trichinella nativa, 1388
Trichinella spiralis (trichinellosis), 1293*t*, 1386–1388
  clinical manifestations of, 1387
  diagnosis of, 1387
  enteric illnesses caused by, 399*t*–405*t*
  eosinophilia from, 1454–1456
  larvae of, 1386
  life cycle of, 1386–1387, 1386*f*–1387*f*
  medical ecology of, 1387–1388
  nurse cell-larva complex and, 1386, 1386*f*
  parasitic myositis from, 475
  prevention of, 1387–1388

- treatment of, 1387

Trichobacteriosis, 439

Trichodysplasia spinulosa, 1107

Trichodysplasia spinulosa-associated polyomavirus, 1105–1107

Trichomonas vaginalis, 1364–1366
- in child abuse, 376
- in children, 1365
- clinical manifestations of, 1365, 1366*b*
- culture of, 358–359
- description of, 1364, 1364*f*
- diagnostic tests for, 1365, 1366*b*
- discharge and dysuria syndrome from, 349, 350*t*
- epidemiology of, 1364–1365, 1366*b*
- laboratory diagnosis of, 1433
- laboratory findings of, 1365
- in lactation, 1365
- in pregnancy, 1365
- prevention of, 1365–1366, 1366*b*
- special considerations for, 1365
- transcription-mediated amplification on, 357
- transmission of, 1364–1365
- treatment for, 1365, 1366*b*
  - infections, 1567
- urethritis from, 357
  - diagnosis of, 358–359
  - in males, 1365
  - treatment for, 359–360
- vaginitis and, 362, 1365

  vulvovaginitis from, 360–362
  wet mount test for, 1365
Trichophyton, preseptal cellulitis and, 519–520
Trichophyton mentagrophytes
  genital dermatosis from, 356
  tinea capitis from, 1282
  tinea corporis from, 1284–1285
  tinea cruris from, 1285
  , tinea pedis from, 1284
  tinea unguium from, 1286
  treatment for, 1532–1533
Trichophyton rubrum
  genital dermatosis from, 356
  tinea cruris from, 1285
  tinea pedis from, 1284
  tinea unguium from, 1286
  treatment for, 1532–1533
Trichophyton schoenleinii, tinea favosa from, 1285
Trichophyton tonsurans
  tinea capitis from, 1282, 1283*f*
  tinea corporis from, 1284–1285
  tinea pedis from, 1284
  treatment for, 1532–1533, 1532*t*
Trichophyton violaceum, tinea capitis from, 1282
Trichosporon beigelii, 1287
Trichostrongylus, 1432
Trichotillomania, 1284
Trichrome stains, 1432

Trichuris trichiura, 1293, 1293*t*, 1377–1378
  - *Campylobacter jejuni* synergy and, 1378
  - clinical manifestations of, 1374*b*, 1377–1378
  - diagnosis of, 1374*f*, 1378
  - eggs of, 1377
  - eosinophilia from, 1454–1456
  - epidemiology of, 1377, 1377*f*–1378*f*
  - infection route of, 1373–1374
  - prevention of, 1378
  - treatment of, 1378

Triclabendazole, 1572
  - for fascioliasis, 1415
  - treatment for
    - fascioliasis (*Fasciola hepatica*), 1572
    - paragonimiasis, 1572

Trifluorothymidine, viral keratitis for, 508

Trifluridine
  - for adenovirus infections, 1100
  - for herpes simplex virus, 499

Trigger points, 188

Trimeric C8 molecule, defects in, in recurrent meningitis, 296

Trimethoprim, 1525–1526
  - adverse effects of, 1587
  - for *Cystoisospora belli*, 1322
  - pharmacokinetics of, 1499*t*–1505*t*

Trimethoprim-sulfamethoxazole (TMP-SMX)
  - adverse reactions of, 1267–1268, 1268*t*
  - in antimicrobial susceptibility testing, 1427

for cholangitis prevention, 421
clinical use of, 1474
for dacryoadenitis, 519
dosing of, 1490*t*–1498*t*
for *Listeria monocytogenes*, 783
mechanism of action of, 1474
for *Proteus mirabilis*, 834
protozoan infections of, 1570
resistance to, 1468*t*, 1474
  Proteus mirabilis, 834
  Shigella infections, 844–845
treatment for
  acute otitis media, 218
  Blastocystis hominis infection, 1572
  Bordetella pertussis, 897*t*
  Cyclospora infections, 1322
  cyclosporiasis, 1572
  cystoisosporiasis, 1572
  Klebsiella (Calymmatobacterium) granulomatis infection, 823–824
  Nocardia infections, 814
  pediculosis, 1296
  pneumonia, in immunocompromised host, 260
  Salmonella infections, 841, 841*t*
  Shigella infections, 845, 845*t*
  Staphylococcus aureus infection, 704
  tickborne infections, 545–546
  Toxoplasma gondii infection, 1359, 1361*t*
  toxoplasmosis CNS disease, 1572

    - urinary tract infections, 345
    - *Yersinia pestis*, 849
- Trimethoprim-sulfamethoxazole exposure, risk factors of, *Stenotrophomonas maltophilia*, 873*b*
- Trimetrexate, for *Pneumocystis jirovecii (carinii)* infections, 1268, 1268*t*
- Triple therapy, treatment for, *Blastocystis*, 1306
- Tripod position, in acute epiglottitis, 213
- Trismus
  - *Clostridium tetani* causing, 996
  - in peritonsillar abscess, 167–168
- Troisier sign, 137
- Trophozoites, 389–390
  - of *Acanthamoeba*, 1339, 1340*f*
  - of *Babesia*, 1298–1299
  - of *Balantioides coli*, 1303
  - of *Endolimax nana*, 1309, 1309*f*–1310*f*
  - of *Entamoeba histolytica*, 1310–1312, 1311*f*
  - of *Giardia intestinalis*, 1317
  - of *Naegleria fowleri*, 1336, 1337*f*
  - of *Plasmodium*, 1342*f*, 1343
  - of *Pneumocystis jirovecii (carinii)*, 1266
  - in stool, examination of, 1432
- Tropical pulmonary eosinophilia (TPE), 1390
- Tropical syndromes, generalized lymphadenopathy from, 132*t*–133*t*, 133–134
- Troponin I
  - in endocarditis, 264
  - in pericarditis, 276

True bacteriologic failure, 207
Trypanosoma
  diagnosis of, in blood smears, 1433
  treatment for, 1568
Trypanosoma (Trypanozoon) brucei, 1366
  African trypanosomiasis, 1366–1369, 1373*b*
  clinical manifestations of, 1368
  CNS disease and, 1368–1369
  description of, 1366–1367, 1367*f*
  diagnosis of, 1368–1369
  epidemiology of, 1367–1368
  pathogenesis and pathology of, 1368
  prevention of, 1369
  prognosis of, 1369
  transmission of, 1367–1368
  treatment of, 1369, 1369*t*
  trypomastigotes of, 1366–1367
Trypanosoma (Trypanozoon) brucei gambiense, 1366
Trypanosoma (Trypanozoon) brucei rhodesiense, 1366
Trypanosoma (Schizotrypanum) cruzi, 1366, 1369
  acute phase of, 1371
  amastigotes of, 1369, 1371*f*
  American trypanosomiasis, 35–36, 1369–1372, 1373*b*
  asymptomatic, 1371
  cardiac manifestations of, 1371
  chronic phase of, 1371
  clinical manifestations of, 1371–1372, 1371*f*
  congenital infection, 1372

  description of, 1369–1370, 1370*f*
  diagnosis of, 1372
  epidemiology of, 1370–1371
  epimastigotes of, 1369
  immune system response against, 1371
  intrauterine infection and, 1372
  pathogenesis and pathology of, 1371, 1371*f*
  pregnancy and, 1372
  prevention of, 1372
  prognosis of, 1371
  transmission of, 1369
    congenital, 1372
  treatment of, 1372
  trypomastigotes of, 1369, 1370*f*
Trypanosoma species (trypanosomiasis), 1366–1373
Trypanosomatidae, 1366–1367
Trypanosomiasis, 1366–1373
Trypanozoon, 1366–1367
Trypomastigotes
  of *Trypanosoma (Trypanozoon) brucei*, 1366–1367
  of *Trypanosoma (Schizotrypanum) cruzi*, 1369, 1370*f*
Tsetse flies, in *Trypanosoma (Trypanozoon) brucei* transmission, 1366
Tsukamurella paurometabola, 789
Tsukamurella pulmonis, 789
Tsukamurella species, 789, 790*b*
Tsukamurella spurrae, 789
Tsukamurella strandjordae, 789
Tsukamurella tyrosinoslovens, 789

Tuberculid reactions, 465

Tuberculin skin test, 799–800

  Calmette-Guérin (BCG) vaccination and, 799

  factors decreasing response to, 799*b*

  false-positive, 799

  interpretation of, 799, 799*b*

  nonreactive, 799

Tuberculoma, 797

Tuberculosis

  BCG vaccine for, 34

  biologic modifier therapy and, 652–653

  in group childcare, 29

  reactivation of, biologic modifier therapy and, 651

  in refugee and internationally adopted children, 34, 35*f*

  TNF-α associated, 653

Tubo-ovarian abscess, 368

Tularemia, 437*t*, 442

  agents, vectors, and geographic distribution of, 543*t*

  clinical and laboratory manifestations of, 544*t*–545*t*, *Francisella tularensis* (tularemia)

Tumefaction, 1289–1290

Tumor necrosis factor-α (TNF-α)

  elevated levels of, in HIV encephalopathy, 671

  Histoplasma capsulatum infections and, 1259

Tumor necrosis factor receptor-associated periodic fever syndrome (TRAPS), 127

  cardinal clinical features of, 127

  course, treatment, and outcome of, 127

  epidemiology and etiology of, 127
Tumor suppressor gene 101 (TSG-101), 1199
Turtles, diseases associated with, 538
22q11.2 deletion syndrome, 639, 640*t*
Twinrix, 81
Tympanic membrane, for measuring core body temperature, 94
Tympanocentesis, 1426
  for acute mastoiditis, 228
  fluid, transport systems and media inoculated routinely in, 1423*t*
Tympanostomy tube placement, chemoprophylaxis after, 1545–1546
Type I error, 5
Type II error, 6
Type III secretion systems
  in *Pseudomonas aeruginosa*, 866, 867*t*
  for *Yersinia*, 846
Typhlitis, 392, 1009
  cancer and, 590–591
Typhoid fever vaccine, 70
Typhoid vaccine, 81
Typhoidal tularemia, F*rancisella tularensis* (tularemia) causing, 924
Typhus, *Rickettsia prowazekii* (epidemic typhus), 958
TYSGM-9 stain, 1433

U

Ulcer(s), 460–466
  aphthous, HIV infection causing, 679
  Blastomyces dermatitidis (blastomycosis) causing, 1272, 1273*f*
  colonic, *Entamoeba histolytica* infection causing, 1310–1312

- in conjunctiva, *Francisella tularensis* infection causing, 924
- cutaneous leishmaniasis and, 1326
- infectious causes of, 461*t*
- *Klebsiella (Calymmatobacterium) granulomatis* and, 823
- noninfectious causes of, 462*t*
- penile, 823*f*
- skin lesions in, 463*t*
- vesicles and bullae and, 448
- visceral leishmaniasis and, 1328

Ulceration
- corneal, *Acanthamoeba* keratitis and, 1339
- skin, *Acanthamoeba* causing, 1339

Ulcerative proctitis, 388

Ulceroglandular disease, F*rancisella tularensis* (tularemia) and, 924

Ulesfia (benzyl alcohol), for pediculosis treatment, 1296

Ultrasonography
- for acute pancreatitis, 419
- for appendicitis, 430
- for cholangitis and cholecystitis, 422
- for *Echinococcus granulosus*, 1406
- fetal, for *Toxoplasma gondii*, 1355, 1355*b*
- for onchocerciasis, 1392
- , for pyogenic arthritis, 488
- for schistosomiasis, 1420
- for transient synovitis, 496

Umbilical stump, neonatal tetanus and, 997

Undecylenic acid, for superficial fungal infections, 1533

UNG deficiency, 622

Upper respiratory tract infections (URTIs), 199, 230
  anaerobic cocci causing, 1018
  HPIV infections and, 1155
  of human metapneumovirus, 1167
  influenza and, 1184
  in internationally adopted children, 36
  viral, clinical manifestations of, 230–231, 231*f*
Urea breath test (UBT), for *Helicobacter pylori* infection, 938, 1427
Ureaplasma, 690
  genital, optimal tests for, 1437*t*–1440*t*
  pneumonia from, 238
Ureaplasma parvum, 1028*t*, 1031
Ureaplasma urealyticum, 357, 1028*t*, 1030–1032
  arthritis from, 491
  clinical manifestations of, 1030–1031
  culture for, 359
  diagnosis of, 1446–1447
    optimal tests for, 1437*t*–1440*t*
    in urethritis, 358–359
  epidemiology of, 1030
  intrauterine and neonatal infection from, 1031
  laboratory findings and diagnosis of, 1031
  microbiology of, 1030
  treatment of, 1032
  urethritis from, 357, 1030–1031
Ureaplasma urealyticum infection, aseptic meningitis from, 303
Urethral discharge
  epididymitis and, 371

  in HSV infection, 1058
  in sexually transmitted infection syndromes, 349
  in urethritis, 358, 359*f*
Urethritis, 357–360
  clinical manifestations of, 358, 358*t*
  complications of, 360
  diagnosis of, 358–359
  differential diagnosis of, 358, 358*t*
  epidemiology of, 357–358
  etiologic agents of, 357
  female patients with, 357
  infectious causes of, 357
  laboratory findings on, 358–359, 359*f*
  male patients with, 357
  Mycoplasma genitalium causing, 349
  nongonococcal (NGU), 357
    Chlamydia trachomatis, *Chlamydia trachomatis*
    Mycoplasma genitalium causing, 357
    Trichomonas vaginalis, *Trichomonas vaginalis*
    Ureaplasma urealyticum causing, 357
  noninfectious causes of, 357
  prevention of, 360
  sexually transmitted infection (STI) pathogens in, 358
  treatment for, 359–360, 360*t*
  Ureaplasma urealyticum causing, 1030–1031
Urinalysis
  for *Plasmodium* infections, 1344–1345
  for urinary tract infections, 344

Urinary catheters, device-associated infections in, 611–612
Urinary specimens, for urinary tract infections, 344
Urinary tract infection (UTI), 78
  atypical, 345
  Bacillus cereus causing, 772
  in burn patients, 530
  Candida spp. causing, 1233–1234
  catheter associated, 348
  circumcision and, 347
  Citrobacter causing, 828
  clinical manifestations of, 344
  coagulase-negative staphylococci (CoNS) causing, 710
  Corynebacterium species causing, 778*t*–780*t*
  definitions of, 343
  diagnosis and management of, 348*b*
  Enterobius vermicularis causing, 1379
  epidemiology of, 343
  etiologic agents of, 343
  fever without localizing signs and, 115*t*
  fungal, 348
  Gardnerella vaginalis causing, 788
  healthcare-associated, 348
  hospital-associated infection and, 561
  imaging evaluation of, 345, 347
  Klebsiella causing, 819
  laboratory findings of, 344–345
  management of, 345–346
    antibiotic prophylaxis as, 346

    - antibiotic resistance as, 345–346
    - antimicrobial treatment as, 345
  - nosocomial, 348
  - pathogenesis of, 343
  - *Proteus* species causing, 834
  - *Pseudomonas aeruginosa* causing, 868*t*
  - recurrent, 347–348
    - anatomic and physiologic abnormalities predisposing, 613*t*
  - renal abscess, complex renal infections and, 343–349
  - risk factors of, 343–344
  - sequelae, and complications of, 346–347
  - *Serratia marcescens* causing, 836
  - special considerations of, 347–348
  - *Staphylococcus saprophyticus* causing, 710
  - urethritis and, 358
- Urine
  - in antigen detection, 1431–1432
  - CMV culture of, 1441
  - collection, 344
  - culture, 344
    - for bacterial infections, in neonate, 553
    - for infected neonate, 548
    - quantitative, 344
  - first-void (FVU), for *Chlamydia trachomatis* detection sample, 1445
  - fishy, aminelike odor, 788
  - specimen-specific isolation methods in, 1426
  - transport systems and media inoculated routinely in, 1423*t*
- Urogenital infections, *Neisseria gonorrhoeae* causing, 762

Urogenital schistosomiasis, 1419

Uropathogens, 345

Urticaria, 455–459

- anaphylaxis with, 456
- clinical manifestations of, 456–458, 457*b*, 458*f*
- complications and prognosis of, 459
- differential diagnosis of, 456–458, 457*b*, 458*f*
- epidemiology of, 455
- etiologic agents of, 455, 456*b*
- infectious agents associated with, 456*b*
- laboratory findings and diagnosis of, 458
- management of, 459
- pathogenesis of, 455–456
- pathologic findings of, 455–456
- *Taenia solium* causing, 1398–1399

Urticaria multiforme, 456

US Advisory Committee on Immunization Practices (ACIP), in influenza immunization, 1187

Uveitis

- anterior, 112, 509–510
  - causes of, 510*t*
  - clinical manifestations of, 509
  - etiologies of, 509–510
- posterior, 510–513

V

Vaccination, Immunization; Vaccine(s)

Vaccine(s)

- adjuvants with, 45
- administration of, 47–50
  - antibody-containing products and, 50
  - corticosteroid use and, 658
  - schedules, 47
  - simultaneous, 47
  - spacing, 47
- adverse events/reactions, case-crossover analysis, 6
- determinants of response to, 45
- financing, 58, 58*t*
- handling and storage of, 58
- host factors of, 45
- immunogenicity of, 45
- immunologic basis of response to, 44
- interchangeability of, 50–51
- licensure and approval of, 46, 46*f*
- measurement of response of, 45–46
- for pneumonia, in immunocompromised host, 261
- routine, childhood and adolescent, 59–69
- safety and compensation for vaccine injury, 51–53
- shortages, 58
- site of administration for, 45
- spacing, 47
- whole organisms, 44, *see also* specific vaccines

Vaccine Adverse Event Reporting System (VAERS), 53, 743

Vaccine Injury Compensation Program, 46

Vaccine-preventable diseases, surveillance for, 59

Vaccine Safety Datalink (VSD), 53

Vaccinia immune globulin, 41

Vaccinia virus, 1049–1052, 1049*t*

  clinical manifestations of, 1050

  epidemiology of, 1049

  laboratory findings and diagnosis of, 1050–1051

  prevention of, 1051–1052, 1052*f*

  treatment for, 1051

Vacuolating cytotoxin (VacA), *Helicobacter pylori* and, 934

Vaginal discharge

  in discharge and dysuria syndrome, 349

  in HSV infection, 1058

  Neisseria gonorrhoeae causing, 761

  Trichomonas vaginalis and, 1365

  in vulvovaginitis, 361, 361*b*

Vaginal specimens, for urethritis, 359

Vaginitis

  Enterobius vermicularis causing, 1379

  in pubertal girls, 362–365

    clinical manifestations of, 362–363

    complications of, 364–365

    differential diagnosis of, 362–363

    epidemiology of, 362

    etiologic agents of, 362

    management of, 363*t*, 364

  Trichomonas vaginalis causing, 1365

Valacyclovir, 1551–1556, 1551*t*

  adverse effects of, 1554

  chemistry of, 1551–1553

  clinical uses of, 1554–1556
  dosage of, 1553–1554
    for impaired renal function, 1490*t*–1498*t*
  for herpes simplex virus, 74
  mechanism of action of, 1551–1553, 1552*t*
  pharmacokinetics of, 1553–1554
  resistance to, 1551–1553, 1552*t*
  spectrum of activity, 1551–1553
  for VZV infections, 1070
Valganciclovir, 1559–1561
  adverse effects of, 1560
  chemistry of, 1559–1560
  for CMV, in solid organ transplant recipients, 570
  dosing of, for impaired renal function, 1490*t*–1498*t*
  mechanism of action of, 1559–1560
  resistance to, 1552*t*, 1559–1560
  spectrum, 1559–1560
Validity, 4
Validity of study, 4
Vancomycin, 742, 1516–1517
  for acute bacterial meningitis, 284
  for acute mastoiditis, 228–229
  for bacterial periorbital cellulitis, 520
  for *Clostridium*, 1011
  for *Clostridium difficile*, 1007–1008
  for dacryoadenitis, 519
  dosage for, 1490*t*–1498*t*, 1527*t*–1531*t*
  for endocarditis, 268

  for endophthalmitis, 515, 516*t*
  Erysipelothrix rhusiopathiae resistance to, 786
  exposure, impact on infection site, 11
  for focal suppurative infections, management, 338
  for infections after burn, 531
  for *Listeria monocytogenes* infections, 784
  for necrotizing enterocolitis, 396
  for orbital infections, 522
  pharmacokinetics of, 1499*t*–1505*t*
  , resistance to, 1468*t*, 1472
    detection of, 1476
    Leuconostoc, 747
    Pediococcus, 747
  spectrum of activity of, 1506*t*–1511*t*
  treatment for
    catheter-associated infection, 701
    coagulase-negative staphylococci (CoNS), 710
    eye infections, 1543*t*
    osteomyelitis, 482
    Staphylococcus aureus, 703
  for viridans streptococci, 734–735
Vancomycin-resistant enterococci (VRE), 731–732
Variance, 2*t*, 5

    - biologic, 1048
    - criteria for, 1044*t*
    - by genomes, 1047*f*–1048*f*
  - detection methods for, 1435–1436
  - exanthems from, 446*b*
  - families, 1044, 1045*t*–1046*t*
  - genome, quantification methods for, 1435–1436
  - isolation of, 1435
  - laboratory diagnosis of, 1434–1445
  - orders, 1048
  - respiratory tract, Respiratory tract viruses
  - skin infections, in cancer, 587
  - species, 1045
  - transmission of, routes of, 1048*b*

Visceral abscesses, 433*t*, 434–435, 436*b*
  clinical manifestations of, 434–435
  etiology of, 434–435
  management of, 435
Visceral larva migrans (VLM)
  Angiostrongylus causing, 1384
  clinical features of, 1382–1383
  diagnosis of, 1383
  Gnathostoma spinigerum causing, 1384–1385
  marine mammal ascarids causing, 1385–1386
  Toxocara and *Baylisascaris* causing, 1381–1384, *Toxocara canis*
Visceral leishmaniasis, 133
Visceral pericardium, 275
Vital signs and habitus, for acute abdominal pain, 173
Vitamin A
  deficiency in, *Shigella* infection treatment, 845
  for rubeola virus infection (measles), 1172–1173
Vitamin B_{12} deficiency
  Diphyllobothrium infection causing, 1395
  Strongyloides fuelleborni causing, 1380
  Strongyloides stercoralis causing, 1380
Vitamin D deficiency, HIV causing, 686
VITEK 2, 1428
Vitrectomy, 516
Vitreous fluid
  aspiration, 515, 515*f*
  culture, 515
  injection, for endophthalmitis, 516*t*

Vocal cord, paralysis of, 166

Voges-Proskauer test, 713

Voiding cystourethrogram (VCUG), for urinary tract infections, 345

Volume depletion, *Vibrio cholerae* infection causing, 876

Volume of distribution (V_d), of drug, 1479

Volvulus, abdominal pain from, 176

Vomiting
- *Borrelia* infections and, 986
- gastrointestinal tract infection and, 377
- norovirus infections causing, 1223
- *Trichinella spiralis* infections causing, 1387
- *Vibrio cholerae* infection causing, 876
- viral gastroenteritis and, 383

Vomitoxin, enteric illnesses caused by, 399*t*–405*t*

Voriconazole, 1537–1538
- in antifungal susceptibility testing, 1432
- clinical experience of, 1538
- dosing of, 1490*t*–1498*t*
- long-term use, mucormycosis association of, 1249
- pediatric data of, 1538
- pharmacology of, 1537–1538
- toxicities of, 1537–1538
- treatment for
  - *Blastomyces dermatitidis* (blastomycosis), 1273
  - *Candida* infections, 1236
  - *Cryptococcus* infections, 1258
  - endophthalmitis, 515, 516*t*
  - eumycotic mycetoma, 1289–1290

    hyalohyphomycosis, 1245–1247
    Pseudallescheria boydii, 1290
Vulnerable child syndrome, 116
Vulvitis, in adolescents, 365
Vulvovaginitis, 356, 360–365, 1232
  clinical approach for, 361
  clinical manifestations of, 361
  complications of, 362
  diagnosis of, 361
  differential diagnosis of, 361
  epidemiology of, 360
  etiologic agents of, 360, 361*b*
  laboratory findings in, 361, 361*b*
  in prepubertal girls, 360–362
  in sexual abuse, 360
  Shigella causing, 844
  treatment of, 361

W

Wakana disease, 1376
Waldeyer ring, 128
Warfarin, treatment for, Kawasaki disease, 1036
Warthin-Starry staining, for *Bartonella* species, 884–885
Warthin-Starry silver, 1427
Warts, cutaneous, HPV associated with, 1103
Wasting syndrome, HIV causing, 672
Water
  Balantidium coli in, 390

  - chlorination of, for *Salmonella* infection prevention, 841
  - chlorine disinfection of, *Naegleria fowleri* prevention, 1338
  - contamination of, infections associated with
    - *Cryptosporidium* in, 1307
    - *Cryptosporidium parvum*, 390
    - *Cyclospora*, 1321
    - *Cystoisospora belli*, 1321
    - *Diphyllobothrium* infection, 1395
    - *E. histolytica*, 390
    - *Giardia intestinalis* (giardiasis), 1318
    - *Legionella*, 948–949
    - *Shigella* transmission, 843
    - *Vibrio cholerae* in, 875–876
  - filtration, for *Giardia* prevention, 1320
  - hot water supply, *Legionella* infections and, 949
  - infections related to, risk and management following, 524*t*
  - precautions for travelers, 1320
  - purification, for *Giardia intestinalis* (giardiasis) prevention, 1320
  - untreated, *Toxoplasma gondii* infection and, 1353
    - prevention of, 1362*t*–1363*t*
- Water filters, 1320
- Waterborne disease, 398–406
  - complications of, 408
  - *Cryptosporidium* in, 398
  - diagnosis of, 407
  - epidemiology of, 398–406
  - management of, 407
  - outbreaks of, 379

Waterborne transmission
  of inflammatory enteritis, 390
  of rotavirus, 1122
Watercress, in fascioliasis, 1415
Weakness, 182–184
  in Guillain-Barré syndrome, 326
  in older children and adults, features of causes of, 183*t*–184*t*
Websites, useful, 1490*b*
Weeksella species, 857–858
Weeksella virosa, 858
Wegener granulomatosis, mediastinal lymphadenopathy from, 155
Weight loss
  in chronic HCV infection, treatment for, 1141
  HIV infection and, 672
Weil-Felix assay, 1433
Weil syndrome, 978, 979*f*, *Leptospira interrogans*
Weil-Felix febrile agglutination test, for *Rickettsia prowazekii*, 959
Welts, 456
West Nile virus (WNV), 183*t*–184*t*, 1130
  aseptic meningitis from, 302
  diagnosis/detection of, 1445
  encephalitis from, 311
    neuroinvasive disease, 311, 322
  optimal tests for, 1437*t*–1440*t*
  retinitis from, 513
Western blot
  for *Borrelia burgdorferi*, 983
  for HIV, 669*t*, 1444

Western equine encephalomyelitis virus (WEEV)
  diagnosis/detection of, 1445
  optimal tests for, 1437*t*–1440*t*
Wet mount test, for *Trichomonas vaginalis*, 1365
Wheezes/Wheezing, 171, 256
  in bronchiolitis, 236
Whiff (amine) test, 788
White, Benjamin, 737
, White blood cell (WBC) count
  for bacillary dysentery, 844
  for brain abscess, 333–334
  for *Chlamydophila (Chlamydia) pneumoniae*, 907–908
  in CSF, for diagnosis of bacterial meningitis, 282
  for human herpesvirus 6, 1084*f*
  for *Mycoplasma pneumoniae* infection, 1025–1026
  for pneumonia, 241
  for transient synovitis, 496
  for *Trichinella spiralis* infections, 1387
  for VZV, 1069
White blood cells, shift to immature forms of, cholangitis and, 422
White piedra, 1287
Whitlow, 441
  herpetic, 534–535, 1058, 1059*f*
Wildlife
  rabies enzootics, 1177, 1178*t*
  Trichinella spiralis infections in, 1386
Wilson disease, 413
  chronic hepatitis and, 416

Wimberger sign, in congenital syphilis, 971, 971*f*
Winterbottom sign, 1368
Wiskott-Aldrich syndrome, 640*t*, 642–643
WNV, West Nile virus
Wolbachia, 1389
Wood lamp examination
  for tinea capitis, 1283
  for tinea pedis, 1284
  for tinea versicolor, 1286
Woolsorters' disease (inhalation anthrax), 770–771
World Health Organization (WHO)
  poliovirus eradication strategies by, 1204
  SAFE, trachoma prevention strategy, 913
  tuberculosis incidence from, 791
Wound
  closure, 535
  transport systems and media inoculated routinely in, 1423*t*
Wound, cellulitis in, 523–525
Wound infections
  Clostridium tetani and, 995, 997
  Edwardsiella tarda causing, 830
  Pasteurella causing, 861
  prophylaxis/treatment for, 1546–1550
  Proteus species causing, 834
  Staphylococcus aureus causing, 696
Wu polyomavirus, 1105–1107
Wuchereria bancrofti, 1293*t*, 1388*t*

X

X-linked agammaglobulinemia (XLA), 620
  persistent or recurrent pneumonia and, 255

X-linked lymphoproliferative syndrome, 640*t*, 643, 1093–1094, 1093*b*

Xanthogranulomatous pyelonephritis, 346–347, 834

Xanthoma cells, 347

Xanthomonas, Stenotrophomonas maltophilia reclassification from, 873

Xenodiagnosis, for *Trypanosoma cruzi* infections, 1372

Xenopsylla cheopis, 848

Xenotropic murine leukemia virus-related virus, chronic fatigue syndrome from, 1038*b*

Xpert MTB/RIF (Xpert), 801

Y

Yaba-like disease virus, 1049*t*

Yaba monkey tumor virus, 1049*t*

Yaws, 976–977
  clinical manifestations of, 976
  diagnosis of, 977
  treatment of, 977

Yeast identification system, API 20C, 1431

Yeast infections
  genital dermatosis and, 355–356
  glucocorticoids as risk factor for, 657

Yeasts, 1229
  exanthems from, 446*b*

Yellow fever, 70

Yellow fever vaccine, 81–82

Yellow fever virus (YFV), 1128

Yersinia, 454, 1010

  isolation of, media used for, 1425*t*

Yersinia enterocolitica, 846–847

  acute abdominal pain from, 175

  clinical manifestations of, 847, 848*b*

  dermatologic manifestations of, 847

  diagnosis of, 848*b*

  enteric disease and, 847

  epidemiology of, 846–847, 848*b*

  etiologic agents, of non-STI infectious GUD, 353

  extraintestinal manifestations of, 847

  in foodborne disease, 398, 399*t*–405*t*

  inflammatory enteritis from, 389, 389*t*

  inguinal lymphadenitis from, 355

  iron overload state from, 647–648

  laboratory findings and diagnosis of, 847

  mediastinal lymphadenopathy from, 151–152

  pharyngitis from, 202

  prevention of, 847

  treatment of, 847, 848*b*

Yersinia enterocolitica infections

  mesenteric adenitis and, 131

  terminal ileitis and, 131

Yersinia pestis, 848–850

  acute bilateral lymphadenopathy lymphadenitis from, 140

  clinical manifestations of, 849, 850*b*

  diagnosis of, in blood smears, 1433

  differential diagnosis of, 849
  epidemiology of, 848–849, 850*b*
  isolation of, media used for, 1425*t*
  laboratory findings and diagnosis of, 849, 850*b*
  prevention of, 850
  treatment of, 850*b*
Yersinia pseudotuberculosis, 847–848
  clinical manifestations of, 848, 848*b*
  epidemiology of, 847–848, 848*b*
  laboratory findings and diagnosis of, 848, 848*b*
  prevention of, 848
  in rodents, 538
  treatment of, 848, 848*b*
Yersinia pseudotuberculosis infections
  mesenteric adenitis and, 131
  terminal ileitis and, 131
Yersinia species, 846–851
  description of, 846
  mesenteric lymphadenitis from, 157
  pathogenesis of, 846
YFV, Yellow fever virus
Yokenella regensburgei, 831

Z

Zanamivir, 1566–1567
  dosing of, for impaired renal function, 1490*t*–1498*t*
  for influenza treatment, 1185
Zidovudine (ZDV), 682*t*

dosing of, 1490*t*–1498*t*
Zika virus (ZIKV), 1130–1131
Zinc, enteric illnesses caused by, 399*t*–405*t*
Zoonotic *Capnocytophaga*, 905
Zoonotic infections, 406
  Ancylostoma caninum causing, 1377
  anthrax, *Bacillus anthracis* (anthrax)
  brucellosis, *Brucella*
  Leptospira causing, 978
  nontraditional pets associated with, 538–539
  poxviruses, Poxviruses, zoonotic
  Trypanosoma (Schizotrypanum) cruzi and, 1369, Animal(s), Pet(s)
Zoonotic influenza, 1188–1189
Zoster, Herpes zoster; Varicella zoster virus (VZV)
Zoster sine herpete, 1068
Zygomycosis, Mucormycosis (zygomycosis)
Zygote, in *Plasmodium*, 1343

Copyright 110
Preface 113
Acknowledgements 116
Dedication 117
Contributors 119
Part I Understanding, Controlling, and Preventing Infectious Diseases 177
- A Epidemiology and Control of Infectious Diseases 178
  - 1 Principles of Epidemiology and Public Health 179
    - Descriptive Epidemiology 179
    - Analytic Epidemiology 184
    - Vaccine Efficacy Studies 200
    - Disease Control and Public Health Policy 201
    - Evaluating the Medical Literature 205
    - Acknowledgments 209
    - References 209
  - 2 Pediatric Healthcare Epidemiology 212
    - Risk Factors for Healthcare-Associated Infections in Children 213
    - Transmission 217
    - Pathogens 220
    - Prevention Programs 223
    - References 258
  - 3 Infections Associated With Group Childcare 270
    - Childcare Settings 272
    - Epidemiology and Etiology of Infections 273
    - Vaccine-Preventable Diseases 292
    - Infections Associated With Animals 293
    - Infectious Diseases in Adults 294

- Economic Impact of Group Childcare Illness 294
- Prevention 295
- References 296

4 Infectious Diseases in Refugee and Internationally Adopted Children 311

- Guidelines for Evaluation 313
- Preventive Measures 325
- References 327

B Prevention of Infectious Diseases 334

5 Passive Immunization 335

- Immune Globulin (Human) 337
- Specific Immune Globulins for Intramuscular Administration 340
- Immune Globulin Intravenous (Human) 343
- Specific Immune Globulins for Intravenous Administration 350
- Monoclonal Antibodies 352
- Immunoglobulin Products Prepared From Animal Plasma 353
- Adverse Reactions to Immune Globulins Prepared From Human Plasma 354
- Product Shortages 357
- The Future 358
